Question	Response
Please submit a plain text version of your cover letter here.	<p>Molly Shoichet, PhD, FRS, O.C., O.Ont. University Professor Molly.shoichet@utoronto.ca 416-978-1460</p> <p>May 10, 2019</p> <p>Floriano Cuccureddu, Editor Advanced Materials</p> <p>Re: Communication, No. adma.201901166 "Benchmarking to the Gold Standard: Hyaluronan-oxime Hydrogels Recapitulate Xenograft Models with In Vitro Breast Cancer Spheroid Culture"</p> <p>Dear Dr. Cuccureddu:</p> <p>We want to thank you and the reviewers for thoughtful consideration of our manuscript. We must admit that we were surprised by your decision to reject our paper based on the reviews, which required only clarification of the text and no new experiments. Moreover, the Reviewers were generally positive, highlighting the importance of validating novel hydrogels for 3D culture – something that we rarely see in the published literature. This burgeoning field is now exploding to include organoid culture, yet the same poor choice of Matrigel is being pursued therein. We have a unique and innovative material that enables critical questions in biology to be answered.</p> <p>While Reviewer #1 suggested that our paper be considered in a sister journal, Reviewer #2 indicated that our paper should be published in this journal; both Reviewers 1 and 2 rated the originality of our submission with an acceptable level of new results; Reviewer #1 rated the scientific and technical content as fully consistent and accurate while Reviewer #2 highlighted only minor inconsistencies; both Reviewers 1 and 2 found the length concise and correct.</p> <p>We have prepared a detailed response and revised our manuscript accordingly.</p>

	<p>We respectfully request that you re-consider your decision and send our revised paper out for re-review. We are confident that this revised paper is clearer and stronger and that the novel chemistry described makes Advanced Materials the most appropriate journal for its publication.</p> <p>Sincerely,</p> <p>Molly Shoichet, PhD, FRS, O.C., O.Ont. University Professor Tier 1 Canada Research Chair, Tissue Engineering</p>
Do you or any of your co-authors have a conflict of interest to declare?	No. The authors declare no conflict of interest.

Abstract:	<p>Many 3D in vitro models induce breast cancer spheroid formation; however, this alone does not recapitulate the complex in vivo phenotype. To effectively screen therapeutics, we urgently need to validate in vitro cancer spheroid models against the gold standard of xenografts. We designed a new oxime-crosslinked hyaluronan (HA) hydrogel, manipulating gelation rate and mechanical properties to grow breast cancer spheroids in 3D. Our HA-oxime breast cancer model maintains the gene expression profile most similar to that of tumour xenografts based on a pan-cancer gene expression profile (comprising 730 genes) of 3 different human breast cancer subtypes compared to Matrigel or conventional 2D culture. Differences in gene expression between breast cancer cultures in HA-oxime versus Matrigel or 2D were confirmed for 12 canonical pathways by gene set variation analysis. Importantly, drug response was dependent on the culture method. Breast cancer cells responded better to the Rac inhibitor (EHT-1864) and the PI3K inhibitor (AZD6482) when cultured in HA-oxime versus Matrigel. This study demonstrates, for the first time, the superiority of an HA-based hydrogel as a platform for in vitro breast cancer culture of both primary, patient-derived cells and cell lines, and provides a hydrogel culture model that closely matches</p>

that in vivo.

53 **Abstract**
54

55
56 Many 3D *in vitro* models induce breast cancer spheroid formation; however, this alone does not
57
58 recapitulate the complex *in vivo* phenotype. To effectively screen therapeutics, we urgently need
59
60
61
62
63
64
65

1
2
3
4 to validate *in vitro* cancer spheroid models against the gold standard of xenografts. We designed a
5
6 new oxime-crosslinked hyaluronan (HA) hydrogel, manipulating gelation rate and mechanical
7
8 properties to grow breast cancer spheroids in 3D. Our HA-oxime breast cancer model maintains
9
10 the gene expression profile most similar to that of tumour xenografts based on a pan-cancer gene
11
12 expression profile (comprising 730 genes) of 3 different human breast cancer subtypes compared
13
14 to Matrigel or conventional 2D culture. Differences in gene expression between breast cancer
15
16 cultures in HA-oxime versus Matrigel or 2D were confirmed for 12 canonical pathways by gene
17
18 set variation analysis. Importantly, drug response was dependent on the culture method. Breast
19
20 cancer cells responded better to the Rac inhibitor (EHT-1864) and the PI3K inhibitor (AZD6482)
21
22 when cultured in HA-oxime versus Matrigel. This study demonstrates, for the first time, the
23
24 superiority of an HA-based hydrogel as a platform for *in vitro* breast cancer culture of both
25
26 primary, patient-derived cells and cell lines, and provides a hydrogel culture model that closely
27
28 matches that *in vivo*.
29

32
33
34

35 36 **Main**

37
38
39 Despite improvements in initial target identification using computational approaches,^[1]
40
41 and several proposed hydrogels to culture cells for the *in vitro* stage of drug discovery,^[2] two-
42
43 dimensional (2D) culture on tissue culture poly(styrene) (TCPS) continues to be used to screen
44
45 cancer therapeutics. 2D culture does not represent the *in vivo* microenvironment either
46
47 mechanically or biochemically, thereby leading to false positive (and likely false negative) drug
48
49 hits.^[3] *In vivo* xenograft tumour models recapitulate human disease more faithfully, but are costly,
50
51 time-consuming and complicated by the use of immunocompromised mice.^[4] The inaccurate but
52
53 rapid and simple method of testing drugs in 2D coupled with the complexity of xenograft models,
54
55 has motivated the development of more representative three-dimensional (3D) culture platforms.
56
57
58
59
60
61
62
63
64
65

1
2
3
4 A suitable 3D culture system must be sufficiently stable for drug screening and benchmarked
5
6 against gold standard *in vivo* xenograft tumour models.^[5] The limited availability of such 3D
7
8 models results in the continued reliance on 2D culture, even with the recognition that 2D culture
9
10 does not accurately predict *in vivo* outcomes.
11
12
13

14
15 Unlike 2D culture, where breast epithelial cancer cells form a monolayer, 3D models of
16
17 cancer recapitulate many disease characteristics such as formation of cancer spheroids with tight
18
19 junctions, and inclusion of key biochemical and mechanical cues of the native extracellular matrix
20
21 (ECM).^[6] Typically, cancer spheroids are formed by growing epithelial cancer cells in 3D using
22
23 non-adherent conditions. This method is rapid and provides remarkable control of the spheroid
24
25 size;^[7] yet, unsurprisingly, the gene expression profiles of these cancer spheroids (CS) formed by
26
27 aggregation resemble cells cultured in 2D more closely than those of xenograft tumours.^[8]
28
29 Therefore, spheroid formation alone does not recapitulate the *in vivo* microenvironment.^[9] Non-
30
31 adherent conditions lack critical ECM components, which both affect cell function through
32
33 integrin-mediated signaling pathways, such as $\beta 1$, and influence drug effectiveness.^[10]
34
35
36
37
38
39

40 Laminin-rich extracellular matrices, such as Matrigel®, which is derived from the
41
42 Engelbreth-Holm-Swarm murine sarcoma, are favored for 3D cell culture as they contain some
43
44 physiologically relevant ECM proteins that mimic the breast tumour microenvironment.^[11]
45
46 However, Matrigel is ill-defined,^[12] and its composition, physicochemical and biomechanical
47
48 properties have limited tunability.^[13] Moreover, Matrigel does not include key matrix components
49
50 found in the breast cancer microenvironment such as hyaluronan (HA), which is produced by
51
52 tumour and stromal cells and is linked to disease progression.^[14] The diversity of cell-surface
53
54 integrin expression and tumour microenvironment properties across breast cancer subtypes require
55
56 a model that is tunable to meet these complexities.^[15]

3
4 The majority of chemically crosslinked hydrogels utilize chemistries that have rapid
5 reaction kinetics,^[16] such as the thiol-Michael addition ligation,^[17] and limit uniform cell
6 encapsulation, making reproducible *in vitro* cell culture challenging. Moreover, many scaffold
7 components need to be stored under inert gas due to air-sensitive functional groups, such as thiols,
8 and/or require external stimuli to promote crosslinking, which complicates scale up.^[18, 19] To
9 achieve a more controlled system for cell encapsulation, we combined fast-reacting HA-aldehyde
10 and slow-reacting HA-ketone with poly(ethylene glycol) (PEG)-oxyamine to create defined 3D
11 hydrogels via oxime click chemistry. Oxime ligation is hydrolytically stable, thereby allowing
12 long-term encapsulation of breast cancer cells – a key advance over current strategies that are
13 inherently limited by reversible reactions of hydrazone or Diels-Alder chemistries for
14 crosslinking.^[20, 21] In addition, the oxime chemistry is insensitive to oxidation, facile to use and
15 enables controlled gelation rates, which is typically not possible with other click chemistry
16 reactions.^[18] We used these newly synthesized oxime-crosslinked HA hydrogels to benchmark the
17 gene expression of breast cancer cells against tumour xenografts grown in mice and evaluate drug
18 response in comparison with conventional culture in Matrigel and 2D TCPS (Fig. 1a).

41 **Synthesis of HA-oxime Hydrogels**

42
43
44 We synthesized HA-oxime gels with HA-ketone (HAK), HA-aldehyde (HAA) and PEG-
45 oxyamine, each component of which first needed to be synthesized. HAK was synthesized, for the
46 first time, in a two-step reaction: (1) amide coupling of 3-(2-methyl-1,3-dioxolan-2-yl)propan-1-
47 amine with 4-(4,6-dimethoxy-1,3,5-triazin-2-yl)-4-methylmorpholinium chloride (DMTMM) as
48 an activator and (2) acid-catalyzed ketone deprotection (Fig. 1b). We found the substitution of
49 ketone to be tunable between $28 \pm 3\%$ and $55 \pm 2\%$ by increasing the equivalents of DMTMM
50 from 1.0 to 2.5, respectively (Fig. S1). We chose to use HAK with approximately 40% ketone
51

61
62
63
64
65

1
2
3
4 substitution to produce hydrogels because it was water soluble and easy to handle. Similarly, we
5
6 synthesized aldehyde-modified HA (HAA) in two steps: (1) amidation of carboxylic acid groups
7
8 on HA with DMTMM/aminoacetaldehyde dimethyl acetal, and (2) deprotection of the resulting
9
10 HA-acetal with aqueous acid (Fig. 1c, Fig S2). The PEG-substituted oxyamine crosslinker was
11
12 prepared from either 4-arm PEG-tetramine or 2-arm PEG-bisamine and (boc-aminoxy)acetic acid
13
14 with carbodiimide coupling followed by acid-catalyzed deprotection to yield PEGOA₄ and
15
16 PEGOA₂, respectively (Fig. S2).
17
18
19
20
21

22 We combined HAK and HAA with PEGOA₄ and laminin (a common extracellular matrix
23
24 protein) to produce crosslinked hydrogels with tunable biochemical properties to grow breast
25
26 cancer spheroids (Fig. 1d). To show that both HAK and HAA biopolymers were crosslinked with
27
28 PEG-oxyamine, we compared the stability of hydrogels comprised of equal weight percent of
29
30 either HAK/HAA or unmodified-HA/HAA crosslinked with PEG-oxyamine: HAK/HAA
31
32 hydrogels remained stable over at least 28 days (with less than 5% decrease in mass) whereas gels
33
34 formed from HA/HAA slowly dissociated, losing $50 \pm 2\%$ of their mass between day 1 and 28,
35
36 reflecting the dissolution of uncrosslinked HA (Fig. S3). Gels crosslinked with four-armed
37
38 PEGOA₄ swelled significantly less than those crosslinked with bifunctional PEGOA₂ (Fig. S3).
39
40 Although both remained intact over four weeks, we used PEGOA₄ in all subsequent experiments
41
42 because the increased swelling of PEGOA₂ crosslinked gels would alter hydrogel mechanical
43
44 properties and hence cell phenotype.^[22]
45
46
47
48
49
50
51

52 **Tunable Gelation of HA-oxime Hydrogels Influences 3D Cell Distribution**

53

54 To achieve uniform 3D cell distribution, hydrogels must form rapidly enough to avoid cell
55
56 aggregation due to gravity during gelation, but slow enough for practical use. HAA only
57
58 crosslinked hydrogels (0:1 HAK:HAA) formed too quickly for cell encapsulation, requiring cells
59
60
61
62
63
64
65

1
2
3
4 to be cultured on top of those gels versus within.^[21] In contrast, hydrogels synthesized with only
5
6 HAK (1:0, HAK:HAA) and PEGOA₄ formed too slowly, with gelation at 87 ± 11 min.
7
8 Consequently, when single breast cancer cells were encapsulated in HAK-only HA-oxime gels,
9
10 cells accumulated in the bottom of the well, due to the slow crosslinking reaction between ketones
11
12 and oxyamines (Fig. 1e). We used rheology to characterize the gelation rate of HA-oxime
13
14 hydrogels with varying HAK:HAA mass ratios (Fig. S4). The gelation rate increased significantly
15
16 with an increasing amount of HAA (Fig. 1f). HA-oxime hydrogels produced with HAK:HAA mass
17
18 ratios of either 7:1 or 3:1, at a constant oxyamine to ketone/aldehyde mole ratio of 0.60, resulted
19
20 in mean gelation times of 35 and 25 min, respectively. At higher weight percentages of the faster
21
22 gelling HAA (HAK:HAA of 1:1), the resulting crosslinked gel formed too rapidly for
23
24 quantification by rheology. We used HAK:HAA of 3:1 in subsequent assays and found a uniform
25
26 distribution of viable cells (Fig. S5). This uniform distribution was maintained for a longer time
27
28 when cells were grown in HA-oxime hydrogels versus those in Matrigel or a commercially
29
30 available HA-based hydrogel, HyStem-C (HA-thiol/gelatin-thiol crosslinked with PEG diacrylate)
31
32 (Fig. S5c).

33 34 35 36 37 38 39 40 41 **Composition-controlled Mechanical Properties and Enzyme-specific Degradation of HA-** 42 43 **oxime Hydrogels**

44
45
46 We were interested in understanding the mechanical tunability of HA-oxime hydrogels in
47
48 relation to Matrigel, the current standard for 3D cell and organoid culture. Matrigel compositions,
49
50 purchased with protein concentrations of 8.50 and 18.43 mg·mL⁻¹, had compressive moduli of 0.9
51
52 ± 0.7 kPa and 1.6 ± 0.4 kPa, respectively, which were not significantly different from each other
53
54 (Fig. 1g). These formulations are typically used for *in vitro* culture and underscore the limited
55
56 mechanical tunability offered by Matrigel.^[23] In contrast, the stiffness of HA-oxime hydrogels
57
58
59
60
61
62
63
64
65

1
2
3
4 varied with the ratio of HAK to HAA. HA-oxime hydrogels are highly tunable over 2 orders of
5
6 magnitude, between 0.3 and 15 kPa, by either varying the crosslinking density or the weight
7
8 percent of HA (Fig. S6). This range covers the stiffness reported for mouse mammary tumours
9
10 (~1.5-4.0 kPa), and human breast cancer tissue (~5-16 kPa), as measured by compression and
11
12 atomic force microscopy, respectively.^[24, 25]
13
14

15
16 HAK-only (1.35 wt%) hydrogels were significantly stiffer (15 ± 1 kPa) than HAA-only
17
18 (1.35 wt%) hydrogels (5.5 ± 0.4 kPa) at a constant mole ratio (0.80) of oxyamine to
19
20 ketone/aldehyde (Fig. S6). We attributed this difference in modulus of HAK-oxime and HAA-
21
22 oxime hydrogels to the difference in molar mass. While we started with the same molar mass of
23
24 HA, synthesis of HAK resulted in a molar mass of $311 \text{ kg}\cdot\text{mol}^{-1}$ whereas that of HAA resulted in
25
26 a molar mass of $122 \text{ kg}\cdot\text{mol}^{-1}$ as measured by gel permeation chromatography. Importantly, there
27
28 was no change in oxyamine to oxime conversion with all HAK and HAA formulations, as
29
30 quantified by ^1H NMR spectroscopy (Fig. S7), further indicating that the molar mass difference
31
32 accounted for the difference in compressive modulus. The stiffness of gel formulations with 3:1
33
34 and 1:1 HAK:HAA weight ratios were not statistically different from Matrigel, so we used 3:1
35
36 ratio for future experiments as it was easier to handle. We found that these HA-oxime gels were
37
38 stable for 28 days when swollen in PBS or when treated with collagenase and degraded only in the
39
40 presence of hyaluronidase, highlighting the enzyme-specific degradability (Fig. 1h). Importantly,
41
42 breast cancer cells are known to produce hyaluronidase, which allows dynamic, cell-based
43
44 spatiotemporal remodeling of the HA-oxime hydrogels during cell growth.^[26]

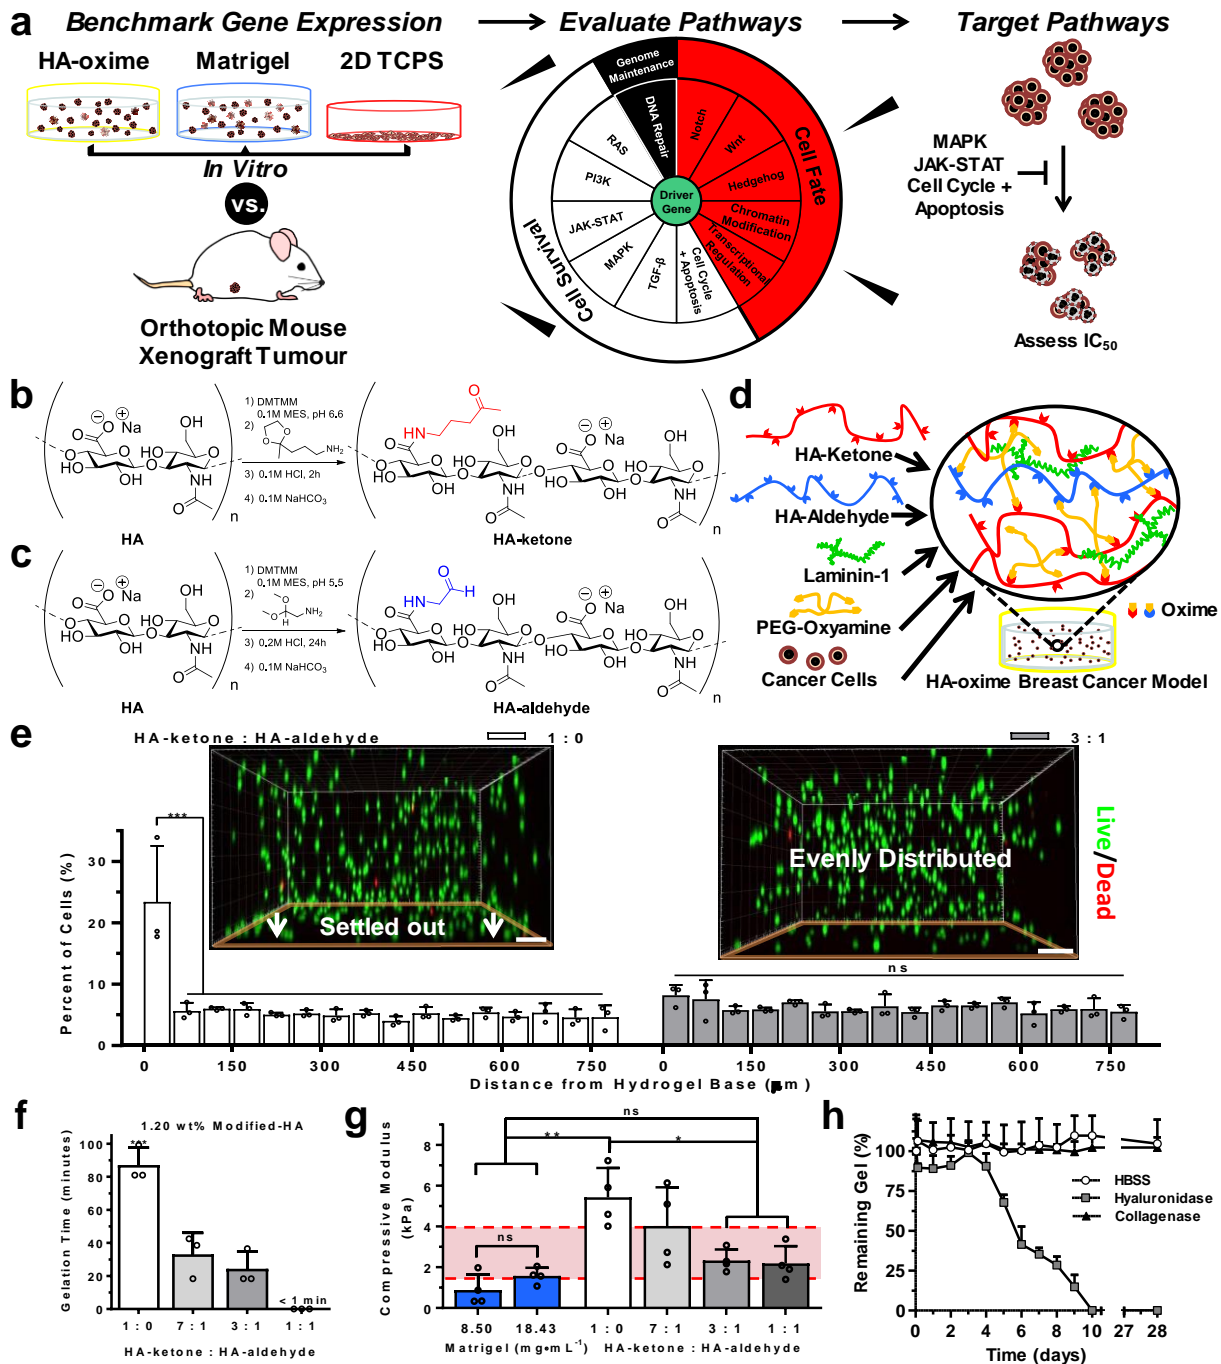

Figure 1. Synthesis and characterization of the HA-oxime hydrogel to model breast cancer in vitro.

(a) The overall goal was to benchmark the gene expression profile of cells cultured in vitro in our novel HA-oxime hydrogels relative to conventional culture in either Matrigel or 2D tissue culture polystyrene (TCPS) to those cells grown in vivo. This methodology allows us to identify pathways

1
2
3
4 that can then be targeted in drug screening assays. (b) Synthesis of HA-ketone using DMTMM
5
6 coupling to HA with 3-(2-methyl-1,3-dioxolan-2-yl)propan-1-amine followed by acid-catalyzed
7
8 deprotection, and neutralization. (c) Synthesis of HA-aldehyde using DMTMM coupling with
9
10 aminoacetaldehyde dimethyl acetal followed by acid-catalyzed deprotection, and neutralization.
11
12 (d) HA-oxime crosslinked hydrogels comprised of HA-ketone (HAK, red), HA-aldehyde (HAA,
13
14 blue), and poly(ethylene glycol)-tetraoxyamine (PEGOA₄, orange) and formed in the presence of
15
16 laminin (green) and breast cancer cells (tan), which resulted in uniformly distributed cells. (e)
17
18 Distribution of encapsulated MDA-MB-468 cells after 24 h in HA-oxime hydrogels: in HAK
19
20 crosslinked gels, cells aggregate at the bottom of the well due to the slow gelation whereas in
21
22 HAK:HAA (3:1 mass ratio), cells are evenly distributed. Cells were stained for viability with
23
24 calcein AM (live, green) and ethidium homodimer-1 (dead, red); scale bar represents 200 μm (n =
25
26 3 independent experiments; mean + s.d. plotted, ***p<0.001, one-way ANOVA, Tukey's post-
27
28 hoc test). (f) Gelation time of HA-oxime hydrogels crosslinked with PEGOA₄ (n = 3, mean + s.d.,
29
30 ***p<0.001, one-way ANOVA, Tukey's post-hoc test). (g) Compressive modulus of HA-oxime
31
32 hydrogels compared to growth factor reduced Matrigel (n = 4, mean + s.d. plotted, *p<0.05;
33
34 **p<0.01, one-way ANOVA, Tukey's post-hoc test). The red shaded area represents the range in
35
36 stiffness of mouse tumours reported in the literature.^[24] (h) HA-oxime hydrogel prepared from 3:1
37
38 HA-ketone (0.90 wt%) and HA-aldehyde (0.30 wt%) crosslinked with PEGOA₄ (1.04 wt%) was
39
40 stable over 28 days at 37 °C in Hank's balanced salt solution (HBSS) and in the presence of
41
42 collagenase, but degraded in the presence of hyaluronidase. The percent of remaining hydrogel
43
44 was determined from the mass measurements (n = 3, mean + s.d. plotted).

1
2
3
4 To mimic the heterogeneity of the extracellular matrix in breast cancer and enhance cell
5 interaction with the HA-oxime hydrogels,^[27] we mixed laminin-1 (Ln) with the polymers prior to
6 gelation and found that it was retained in the gels obviating the need for covalent immobilization:
7 Ln incorporated at either 75 or 250 $\mu\text{g}\cdot\text{mL}^{-1}$ was completely retained in hydrogels after 7 days,
8 with no soluble Ln detected in the PBS supernatant (Fig. 2a). Given the large size of Ln (850 kDa),
9 it was likely physically entrapped or entangled within the HA-oxime polymer chains, but may have
10 also be retained by either (or both) electrostatic interactions between positively charged Ln and
11 negatively charged hyaluronan-carboxylate groups^[28] or reversible Schiff-base formation between
12 basic lysine groups on laminin and HA-ketone/aldehyde groups.^[29] The interactions between
13 laminin and HA-oxime hydrogels did not alter the compressive modulus compared to HA-oxime
14 only hydrogels thereby enabling the role of ECM proteins to be studied separately from mechanical
15 properties (Figs. S8a).

16

24
25
26
27
28
29
30
31
32
33 To investigate cell-Ln interactions, we compared cell adhesion to HA-oxime gels with or
34 without Ln and found more than 2-times more T47D luminal A breast cancer cells adhered to the
35 surface of hydrogels containing 75 $\mu\text{g}\cdot\text{mL}^{-1}$ Ln, similar to Matrigel versus controls without Ln
36 (Fig. 2b). With or without Ln, breast cancer cells encapsulated in HA-oxime hydrogels were
37 equally viable and evenly distributed, and the size and number of spheroids were similar (Fig. S8b-
38 i). Cells within the spheroids interacted with each other, as demonstrated by E-cadherin expression,
39 a marker of tight junctions (Fig. 2c-d). Cells also interacted with the HA-oxime hydrogel through
40 CD44, a hyaluronan receptor, and expressed $\beta 1$ -integrin, a Ln receptor (Fig. 2e-h). CD44 is
41 essential to the growth of breast cancer cells and $\beta 1$ -integrin is involved in the PI3K pathway,
42 which is upregulated in breast cancer and constitutes a drug target.^[30] We observed some evidence
43 of HIF-1 α expression, a marker for either reactive oxygen species or hypoxia typically observed
44
45

1
2
3
4 in breast cancer tumours (Fig. 2i-j). The HIF-1 α expression observed at the periphery of the
5
6 spheroids has been observed in other cancer spheroids and likely represents reactive oxygen
7
8 species versus hypoxia at the core because oxygen can diffuse through the ~ 70 μm diameter
9
10 spheroids (Fig. S9).^[31] Given the relevance of hyaluronan in breast cancer^[32] and the interaction
11
12 of cells with the HA-oxime hydrogels, we wondered whether culture in HA-oxime with or without
13
14 laminin would impact the gene expression levels compared to those in Matrigel and conventional
15
16 2D TCPS.

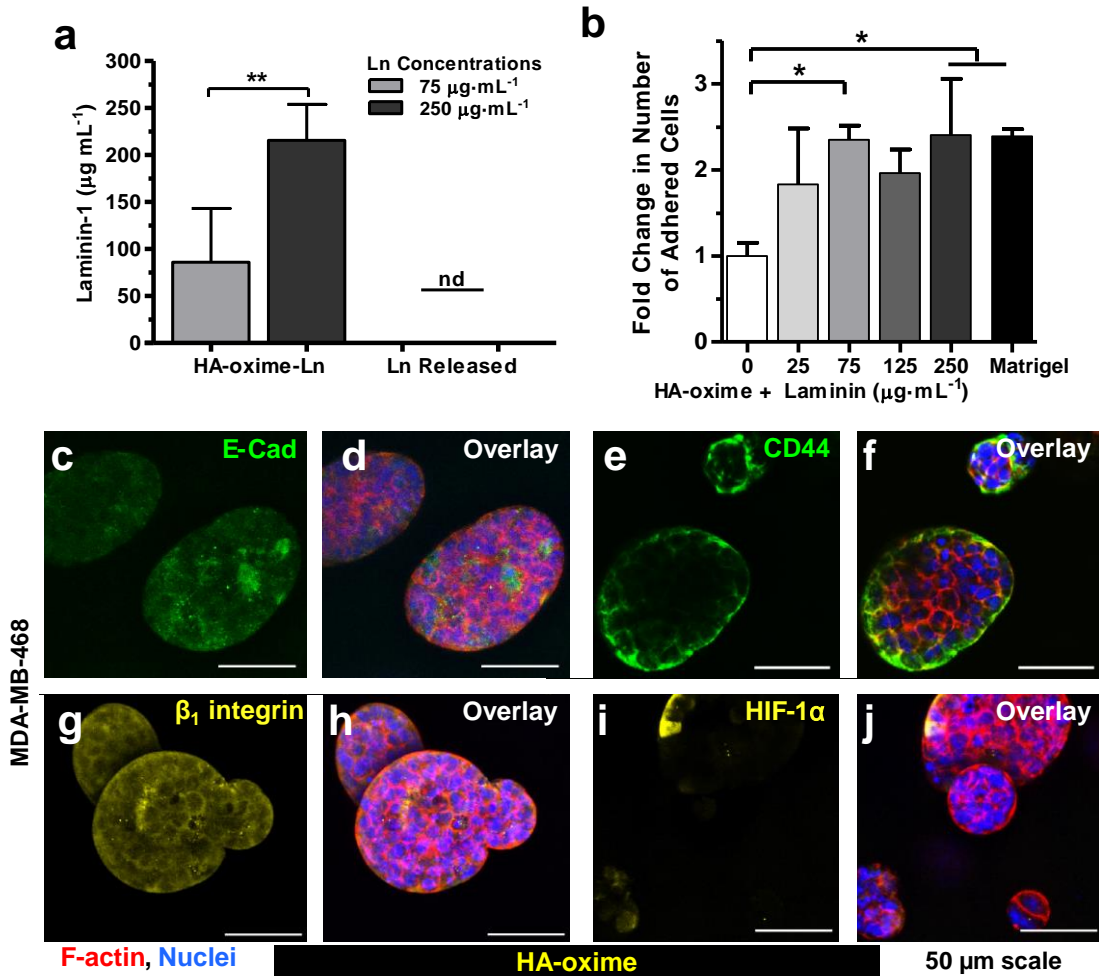

Figure 2. Impact of laminin in HA-oxime hydrogels. (a) The amount of Ln retained in HA-oxime hydrogels crosslinked with PEGOA₄ quantified by ELISA after 7 days, Ln was not detected (nd) from supernatant 24 h after adding PBS to HA-oxime-Ln hydrogels (n = 3 independent samples;

22 **HA-oxime Hydrogels Enable Spheroid Formation of 5 Different Breast Cancer Cell Lines** 23 24 **and Patient-derived Primary Breast Cancer Cells** 25 26

27 When cells from 5 different breast cancer cell lines were cultured for 21 days in HA-oxime
28
29 hydrogels +/- Ln they formed spheroids, which was not observed in 2D culture (Fig. S10). These
30
31 cells represent 4 breast cancer subtypes with different expression profiles of estrogen receptor
32
33 (ER), progesterone receptor (PR), and human epidermal growth factor receptor 2 (HER2): luminal
34
35 A MCF7 and T47D (ER⁺, PR⁺, HER2⁻), luminal B BT474 (ER⁺, PR⁺, HER2⁺), HER2-
36
37 overexpressing MDA-MB-231-H2N (ER⁻, PR⁻, HER2⁺), and triple negative MDA-MB-468 (ER⁻,
38
39 PR⁻, HER2⁻) cells. By examining proliferation in 2D and 3D, and between different hydrogel
40
41 cultures, we observed that all breast cancer cell lines exhibited similar proliferation rates in HA-
42
43 oxime +/- Ln hydrogels compared to Matrigel except BT474 cells, where proliferation was
44
45 increased in Matrigel (Fig. 3a). In addition, all cells formed spheroids of similar diameter ~100
46
47 μm , suitable for oxygen and nutrient penetration^[33] at 21 days in HA-oxime hydrogels and
48
49 Matrigel (Fig. 3b), indicating phenotypic equivalence at minimum.
50
51
52
53
54
55
56

57 Recent efforts to develop *in vitro* cancer models that recapitulate the features of human
58
59 breast cancer for preclinical testing or personalized medicine have used poorly-defined Matrigel
60
61
62
63
64
65

1
2
3
4 to grow 3D tumour organoids. To test the HA-oxime hydrogel for these applications, we
5
6 encapsulated patient-derived primary luminal B breast cancer cells in 3D therein and observed
7
8 their survival and proliferation: the patient-derived cells grew as spheroids in the hydrogel but
9
10 proliferated as monolayers on 2D TCPS (Fig. S11). Impressively, encapsulated primary breast
11
12 cancer cells from a dissociated patient biopsy formed spheroids in both HA-oxime +/- Ln and
13
14 Matrigel after 21 days of culture (Fig. 3c-f). It is possible that over the 21 days of culture within
15
16 the 3D hydrogel, glucose and/or oxygen gradients will form and result in heterogeneity that more
17
18 closely mimics the tumour microenvironment within the xenograft versus that of 2D TCPS. These
19
20 results led us to perform a more extensive comparison of gene expression between the mouse
21
22 xenografts and *in vitro* models in order to better understand the biological differences between
23
24 these *in vitro* models.
25
26
27
28
29
30
31

32 **Gene Expression of 5 Distinct Breast Cancer Cell Lines Cultured *In Vitro* vs. In Vivo Growth** 33 34 **as Tumour Xenografts** 35 36

37 In order to understand how breast cancer markers and drug-targetable pathways are
38
39 impacted by culture platform, we benchmarked the gene expression of 5 cell lines cultured in HA-
40
41 oxime +/- Ln against orthotopic mouse xenografts in NOD SCID gamma mice and compared them
42
43 to those in Matrigel or 2D TCPS (Fig. S12, S13). In general, the gene expression of breast cancer
44
45 cells cultured in either HA-oxime hydrogels +/- Ln or Matrigel were more similar to that of mouse
46
47 xenograft models than cells cultured on 2D TCPS (Fig. 3g). Several genes were differentially
48
49 expressed compared to tumour xenografts when cultured on 2D TCPS, but not when cultured in
50
51 HA-oxime hydrogels, including epidermal growth factor receptor (EGFR), human epidermal
52
53 growth factor receptor 2 (ERBB2) and phosphatidylinositol-4,5-bisphosphate 3-kinase catalytic
54
55 subunit alpha (PIK3CA) which are implicated in drug targetable pathways (Table S1). The
56
57
58
59
60
61
62
63
64
65

1
2
3
4 expression of both ERBB2 and EGFR can result in changes to cell phenotype and tumorigenicity,
5
6 and may also influence response to therapy, including agents targeting these receptors directly.^[34]
7
8
9 In addition, patients with PIK3CA-positive breast tumours have shorter disease-free survival
10
11 across all molecular subtypes indicating its potential as a therapeutic target.^[35] Thus, these results
12
13 further underscore the need to use representative 3D models to study breast cancer over traditional
14
15 2D culture.
16
17

18
19 A potential strategy for treating breast cancer beyond traditional kinase inhibitors includes
20
21 emerging metabolic targets such as FASN, which is responsible for lipid synthesis. Currently, the
22
23 FASN inhibitor TVB-2640 is being evaluated for the treatment of advanced breast cancer in a
24
25 clinical trial.^[36] Due to observed differences in cellular fatty acid and cholesterol content between
26
27 2D culture and xenograft models,^[37] we hypothesized that the expression of lipid metabolic genes
28
29 would be more similar in 3D cell culture than 2D culture relative to the xenograft tumours. The
30
31 expression of FASN, which is responsible for lipid synthesis, and ATP-binding cassette transporter
32
33 (ABCA1), which regulates intracellular phospholipid and cholesterol homeostasis, depended upon
34
35 both cell line and culture system. For example, luminal A MCF7 cells had similar ABCA1 and
36
37 FASN expression between tumour xenograft and HA-oxime hydrogel culture, but an upregulated
38
39 FASN expression when cultured on 2D TCPS or Matrigel (Fig. 3g). This shows that FASN
40
41 expression is influenced by the ECM and that gene expression levels of xenograft tumours for
42
43 luminal A breast cancer were recapitulated using the HA-oxime hydrogel. However, HER2-
44
45 overexpressing MDA-MB-231-H2N cells upregulated FASN and ABCA1 across all *in vitro*
46
47 models, which suggests altered lipid metabolism and secretion compared to xenograft tumours.
48
49 These differences in FASN expression were not observed for other breast cancer subtypes, which
50
51 supports breast cancer subtype-dependent lipid metabolism in 2D.^[38] Considering the similar gene
52
53
54
55
56
57
58
59
60
61
62
63
64
65

expression of breast cancer cells cultured in HA-oxime hydrogels and grown as xenograft tumours, we performed more rigorous benchmarking with a pan-cancer gene expression panel.

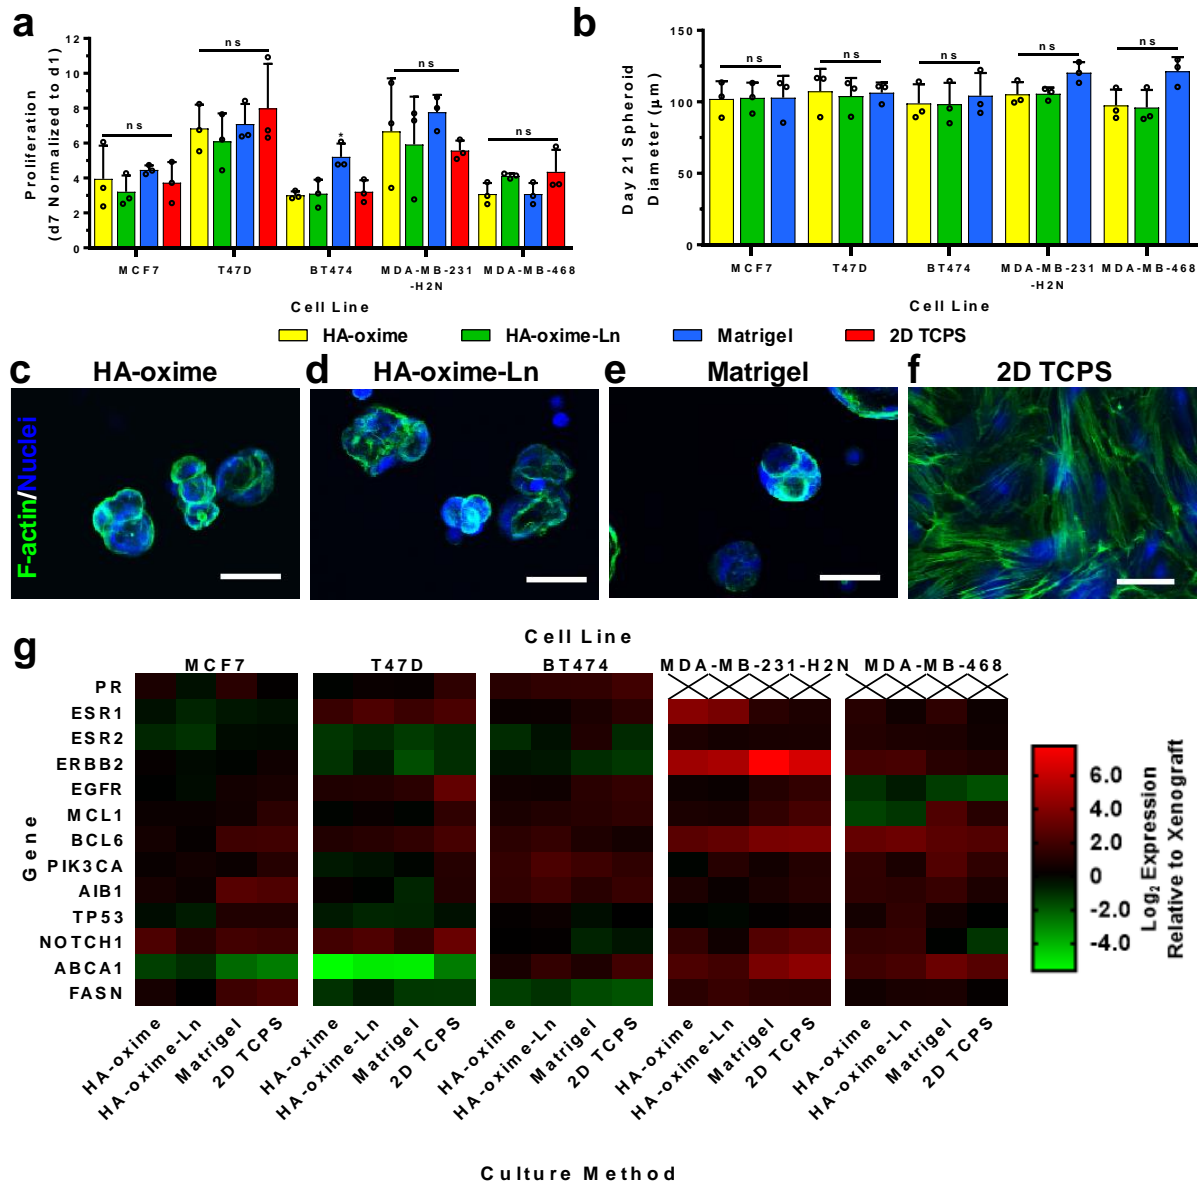

Figure 3. Evaluation of patient-derived and 5 different breast cancer cell lines in HA-oxime +/- Ln versus Matrigel and 2D TCPS. (a) Cell growth at day 7 relative to day 1 (n = 3; mean + s.d. plotted, *p<0.05, one-way ANOVA, Tukey's post-hoc test). (b) Tumour spheroid diameter after 21 days of culture for cells embedded in HA-oxime, HA-oxime-Ln or Matrigel (n = 3; mean + s.d. plotted, *p<0.05, one-way ANOVA, Tukey's post-hoc test). No spheroids were formed on 2D

13
14 days and compared to the respective mouse xenograft tumours. Expression reported as the Log_2
15
16 ratio from qPCR with black indicating the greatest similarity (n = 3-5 independent studies; mean
17
18 plotted).

23 24 **Pan-Cancer Gene Expression Benchmarks *In Vitro* Breast Cancer Models**

25
26
27 In order to better understand the predictive powers of 3D *in vitro* culture of breast cancer
28
29 cells, we benchmarked 3 distinct cell lines, representing 3 different breast cancer subtypes, to
30
31 tumour xenografts: luminal B (BT474); HER2-overexpressing (MDA-MB-231-H2N); and triple
32
33 negative (MDA-MB-468). We cultured cells in 3D in HA-oxime, Matrigel or in 2D on TCPS and
34
35 compared the gene expression panel of 730 cancer-related genes. Relative to tumour xenografts,
36
37 we found that luminal B, BT474 cells had the fewest number of differentially expressed genes
38
39 when cultured in HA-oxime gels (24 downregulated and 27 upregulated of 730 genes) compared
40
41 to those cultured in Matrigel (63 downregulated and 135 upregulated) and on 2D TCPS (60
42
43 downregulated, 45 upregulated) (Fig. 4a, b, Table S2). Surprisingly, there were more differences
44
45 when cells were cultured in Matrigel than on 2D TCPS relative to xenografts, which both reflects
46
47 the unsuitability of Matrigel and demonstrates that 3D culture alone is insufficient for predictive
48
49 drug screening.

50
51
52 We analyzed 12 pathways and driver genes by gene set variation analysis and found that
53
54 BT474 cells cultured in Matrigel altered the expression of several pathways including JAK-STAT
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 and MAPK versus tumour xenografts whereas cells cultured in HA-oxime gels did not (Fig. 4c).
5
6 This further motivates the use of representative, benchmarked 3D *in vitro* models, such as the HA-
7
8 oxime hydrogel, to recapitulate gene expression and to evaluate new drug candidates against JAK-
9
10 STAT and MAPK.^[39]
11
12

13
14 Comparing the gene expression of MDA-MB-231-H2N tumours to 3D hydrogels and 2D
15
16 culture, we found that fewer genes were differentially expressed when cells were grown in HA-
17
18 oxime gels (16 downregulated, 12 upregulated) versus both Matrigel (28 downregulated, 21
19
20 upregulated) and 2D TCPS (33 downregulated, 29 upregulated) (Fig. 4d, e, Table S3). Altered
21
22 gene expression of a therapeutic target in cells used in an *in vitro* drug screen would generate
23
24 misleading data. Differences in the JAK-STAT pathway were identified between cells cultured in
25
26 HA-oxime, Matrigel or 2D TCPS relative to the tumour xenografts after analyzing the pathways
27
28 regulating cell survival and cell fate between the *in vitro* models and tumour xenografts of MDA-
29
30 MB-231-H2N cells (Fig. 4f).
31
32
33

34
35
36 When triple-negative breast cancer (TNBC) MDA-MB-468 cells were cultured in HA-
37
38 oxime gels, Matrigel or 2D TCPS, a similar number of genes were downregulated compared to the
39
40 xenograft tumours (125, 134 and 122, respectively) while the number of upregulated genes was
41
42 higher in 2D TCPS (94) versus HA-oxime and Matrigel (60 and 54 genes, respectively) (Fig. 4g,
43
44 h, Table S4). Subsequent analysis of affected pathways revealed that the hedgehog pathway was
45
46 altered when cultured in HA-oxime, Matrigel or 2D TCPS relative to the tumour xenografts (Fig.
47
48 4i). Since only 30% of triple-negative breast cancers involve paracrine hedgehog (Hh) signalling,
49
50 which has been studied in the context of cancer-associated fibroblasts, co-culture models may be
51
52 required to target this pathway.^[40]
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 Our gene expression pathway analyses show that the JAK-STAT pathway was altered in
5
6 both HER2⁺ BT474 and MDA-MB-231-H2N cell lines when cultured in Matrigel or on 2D TCPS
7
8 relative to xenograft and HA-oxime. This underlines the need to evaluate drugs targeting specific
9
10 pathways on validated models. Remarkably, while Matrigel is thought to be the gold standard for
11
12 in vitro culture, it has not been benchmarked previously and our data clearly demonstrate that it is
13
14 sub-optimal. Overall, HA-oxime gels were the most similar to xenografts, with only 294
15
16 differentially expressed genes vs. 434 for Matrigel and 371 for 2D TCPS (Figure 4j, Fig. S14).
17
18
19 The number of differentially expressed genes for the same cell lines was similar between HA-
20
21 oxime and HA-oxime-Ln hydrogels (294 versus 308 genes, respectively) compared to the
22
23 xenograft tumours (Fig. S14b). Thus, 3D culture reduces, but does not eliminate, differences in
24
25 gene expression between 2D culture and xenografts. 3D culture in HA-oxime better emulates the
26
27 gene expression profile of xenografts than culture in Matrigel.

17 genes after culture in HA-oxime, Matrigel, or 2D TCPS versus mouse xenograft tumours for
18 BT474, MDA-MB-231-H2N, and MDA-MB-468 cells (n = 3 except for BT474 cells grown in
19 Matrigel where n = 4).

20 21 22 23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 **Evaluating Differences in Drug Response Between 2D and 3D Models**

45
46
47 To understand if these differences in gene expression could influence cell response in drug
48 screening, we specifically chose drugs that target pathways differentially expressed between
49 xenograft and *in vitro* culture in Matrigel and 2D TCPS and that were not differentially expressed
50 in HA-oxime (Table S4, S5). We tested a series of drugs that target the MAPK (such as Rac
51 signaling) and JAK-STAT pathways of BT474 cells grown in HA-oxime vs. Matrigel and 2D
52 TCPS.
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 BT474 cells treated with EHT-1864 (Rac inhibitor, targeting the MAPK/ERK pathway)
5
6 were more responsive when cultured in HA-oxime than in Matrigel (Fig. 5a, Fig. S15). In addition,
7
8 BT474 cells cultured in HA-oxime were more responsive to AZD6482 (PI3K β inhibitor involved
9
10 in the JAK-STAT pathway) than those cultured in Matrigel or on 2D TCPS (Fig. 5b). To gain
11
12 biological insight into the mechanism underlying the observed differences in drug responsiveness,
13
14 we quantified the number of genes involved in MAPK and JAK-STAT signaling pathways with
15
16 differential expression levels relative to tumour xenografts: cells cultured in HA-oxime had fewer
17
18 differentially expressed genes (14 for MAPK and 4 for JAK-STAT) compared to cells cultured in
19
20 both Matrigel (43 for MAPK and 29 for JAK-STAT) and on 2D TCPS (23 for MAPK and 10 for
21
22 JAK-STAT) (Fig. 5c-e, red circles for MAPK and green circles for JAK-STAT). Together these
23
24 results demonstrate the superiority of HA-oxime over Matrigel and 2D TCPS in drug screening
25
26 where specific pathways are targeted.
27
28
29
30
31
32

33
34 Interestingly, cells cultured in HA-oxime were over tenfold more sensitive to maritoclax
35
36 (Fig. S15c), an Mcl-1 inhibitor which prevents the normal anti-apoptotic signaling by Mcl-1 on
37
38 the mitochondria resulting in apoptosis, with an IC₅₀ of 0.59 μ M than those cultured in 2D TCPS
39
40 with IC₅₀ of 5.5 μ M (Fig. 5f). Moreover, primary, human patient tumour luminal B breast cancer
41
42 cells were significantly more sensitive to maritoclax when cultured in 3D HA-oxime than those
43
44 cultured on 2D TCPS as well, demonstrating both the potential of the HA-oxime hydrogels in
45
46 personalized medicine and the importance of culture conditions in drug screening (Fig. S16).
47
48 Maritoclax targets the apoptosis pathway as an inhibitor of anti-apoptotic protein Mcl-1 on the
49
50 mitochondria. Regulators of this apoptosis pathway, BAD (pro-apoptotic) and BCL2 (anti-
51
52 apoptotic), had decreased levels in BT474 cells cultured on 2D TCPS relative to 3D culture, which
53
54 explains the observed differences in drug response (Fig. 5g).
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 We highlight the results of the *in vitro* drug screening performed with BT474 cells where
5
6 IC_{50} values differed between HA-oxime, Matrigel and 2D TCPS (Fig. 5h). Since the decision to
7
8 test drugs in animal models of disease is often based on *in vitro* screening, maritoclax, EHT-1864
9
10 and AZD6482 would have been excluded based on culture in Matrigel and/or 2D TCPS, thereby
11
12 reflecting the importance of culture in a representative matrix, such as HA-oxime. The differences
13
14 between 2D and 3D culture of breast cancer cells are significant in terms of gene expression and
15
16 drug response. While cell response did not always differ between the 3 culture conditions (as
17
18 shown with ZSTK474 and afatinib, Fig. S15), to ensure comprehensive screening, a validated,
19
20 representative system, like HA-oxime, is required.

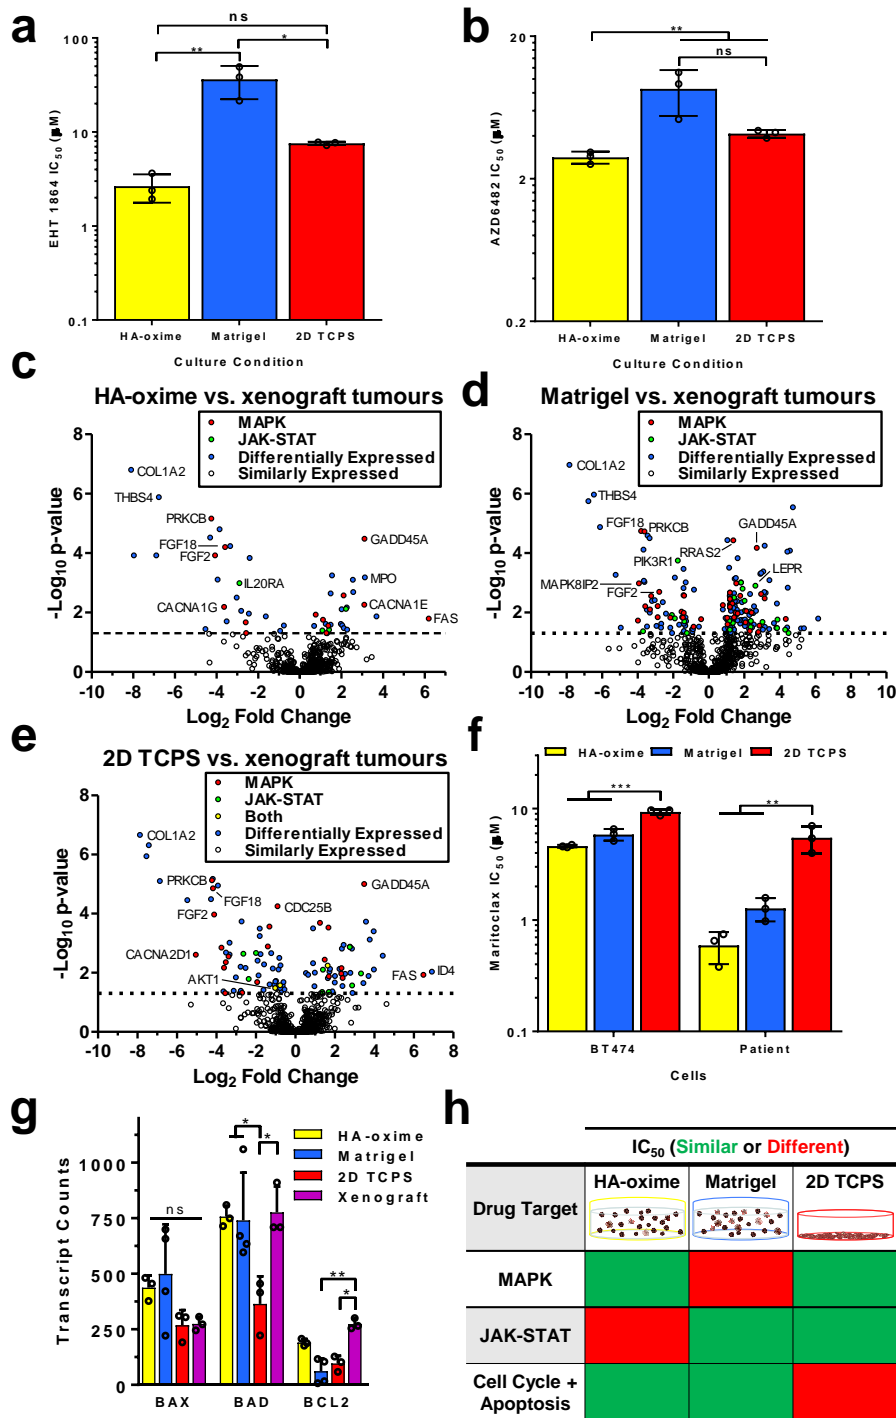

Figure 5. Targeting pathways in BT474 breast cancer cells cultured *in vitro* with drugs. (a, b) IC_{50} values for BT474 cells cultured *in vitro* treated with (a) EHT 1864 targeting the MAPK pathway or (b) AZD6482 targeting the JAK-STAT pathway (n = 3 independent experiments; mean +

1
2
3
4 standard deviation plotted, * $p < 0.05$, ** $p < 0.01$, by one-way ANOVA, Tukey's post-hoc test). (c-
5
6 d) Volcano plots of differentially expressed genes involved in MAPK signalling (red), JAK-STAT
7
8 signalling (green), both pathways (yellow), other (blue) and similarly expressed (white) when
9
10 cultured in (c) HA-oxime, (d) Matrigel or on (e) 2D TCPS versus tumour xenografts. (f) IC_{50}
11
12 values for BT474 and patient derived breast cancer cells cultured *in vitro* treated with maritoclax
13
14 targeting the apoptosis pathway (n = 3 independent experiments; mean + standard deviation
15
16 plotted, ** $p < 0.01$, *** $p < 0.001$ by one-way ANOVA, Tukey's post-hoc test). (g) Gene expression
17
18 counts of apoptosis signalling genes BAX, BAD and BCL2 for BT474 cells cultured *in vitro* or as
19
20 tumour xenografts. (h) Summary of observed statistical differences in IC_{50} values from drug
21
22 screening with EHT 1864 (which targets MAPK), AZD6482 (which targets JAK-STAT) and
23
24 maritoclax (which targets apoptosis) with BT474 cells cultured in HA-oxime, Matrigel or on 2D
25
26 TCPS. IC_{50} values that were statistically different depending on culture platform are shown in red
27
28 while those which were not statistically different are shown in green.

34
35
36

37 To gain insight into the broader utility of the HA-oxime hydrogels with other cell types,
38
39 we investigated the efficacy of erlotinib, an EGFR inhibitor, against TNBC MDA-MB-468 cells.
40
41 Cells that were grown on 2D TCPS, in Matrigel or HA-oxime for 21 days and treated with erlotinib
42
43 for 7 days had a significantly higher IC_{50} of 37.6 μM ($p < 0.01$) compared to those cultured in 3D
44
45 of $\sim 4.5 \mu\text{M}$ (Fig. S17). MDA-MB-468 cells cultured on 2D were less sensitive to erlotinib than
46
47 other cancer cell lines, despite its established effectiveness in breast cancer xenografts in mice,^[41]
48
49 further highlighting the importance of relevant screening assays.
50
51
52
53

54 **Conclusions**

55
56 3D cell culture has several features which make it attractive for drug screening, yet is limited by
57
58 the use of Matrigel, which does not faithfully recapitulate the gene expression profile of the tumour
59
60
61
62
63
64
65

1
2
3
4 xenograft and is chemically ill-defined. The newly synthesized HA-oxime hydrogels have
5
6 controlled and tunable gelation, mechanical properties, and chemical properties that mimic the
7
8 breast ECM, which are not possible with 2D TCPS and limited with Matrigel. By benchmarking
9
10 to the *in vivo* gold standard for the first time, we demonstrate that breast cancer cells grown in HA-
11
12 oxime hydrogels most closely resemble orthotopic xenografts in terms of gene expression profiles
13
14 of 3 distinct breast cancer subtypes. This impacts the value of *in vitro* drug screening. Formulating
15
16 the HA-oxime hydrogels with laminin did not reduce the number of differentially expressed genes
17
18 expressed by the breast cancer spheroids compared to the tumour xenografts. Our analysis of
19
20 canonical signaling pathways using the gene expression data suggest breast cancer subtype-
21
22 dependant changes to gene expression with culture platform. We demonstrated the ability to grow
23
24 patient-derived breast cancer cells in HA-oxime hydrogels and thereby identify relevant drug
25
26 candidates. Thus, hyaluronan-oxime hydrogels bridge the gap between 2D drug screening *in vitro*
27
28 and *in vivo* mouse xenograft models, opening the door to personalized medicine and more
29
30 predictive drug screening. To take full advantage of this opportunity, scale up and simultaneous
31
32 screening of multiple drugs is required. This well-defined hydrogel platform opens up the
33
34 possibility for more complex 3D models with co-culture of multiple cell types, thereby better
35
36 emulating the complexity of tumours.
