Abstract:

The design and development of non-precious metal catalysts with high activity and stability for overall water splitting remains a major challenge. Herein, lamellar FeNi₃N incorporated by FeNi₃ is synthesized via thermal ammonolysis. The abundance of hollow sites in this FeNi₃-FeNi₃N heterostructure significantly enhances the intrinsic activity towards hydrogen evolution reaction, while the heterostructure also offers high electrochemical active surface area for oxygen evolution reaction. FeNi₃-FeNi₃N enables a lower overpotential for both hydrogen and oxygen evolution

electrocatalysis in alkaline media. When FeNi₃-FeNi₃N is employed as a bifunctional material for overall water splitting, it shows a cell voltage of only 1.5 V at 10 mA cm⁻² and offers stable performance for up to 48 h at current densities of ~40 mA cm⁻².

Introduction

Electrochemical water splitting is a promising, sustainable technology to enable energy conversion and high purity hydrogen production. This is so significant since it can be a means to achieve comprehensive utilization of renewable resource-derived electricity.¹ The efficiency of electrochemical water splitting depends primarily on electrode catalysts for both anodic oxygen evolution reaction (OER) and cathodic hydrogen evolution reaction (HER).²⁻⁴ In typical acidic media, the electrode materials deployed until now are generally noble metal-based materials, which suffer from high overpotential, cost and vulnerability.⁵ On the contrary, although the output power of overall water splitting in alkaline medium is two orders of magnitude lower than that in acidic solution,⁶⁻⁷ the low overpotentials achieved on earth-abundant transition metal materials make overall alkaline water splitting more efficient and economical.

Nickel/iron based compounds (including alloys,¹¹ layer double hydroxide,¹² nitrides,¹³ oxides,¹⁴ sulfides,¹⁵ phosphides,¹⁶ carbides¹⁷⁻¹⁸) have been known to be active OER catalysts. Among these materials, the as-formed NiOOH site is commonly regarded as the active center, and the incorporation of Fe suppresses the oxidation of Ni²⁺; leading to Ni^{3+/4+} with more oxidizing power and thus resulting in faster OER

kinetics.^{12, 19-21} It is reported that the number of Ni^{2+} ions that get converted into Ni^{3+} ions (NiOOH) is equal to the number of Ni sites that actually catalyze the OER;²² this allows the accurate determination of density of active sites via a redox peak method.²² To further simplify the electrochemical system and speed up the commercialization of alkaline water splitting, the efficient bifunctional electrocatalysts that simultaneously catalyze HER and OER in alkaline media is desirable.⁸⁻¹⁰ However, due to the inappropriate (either too strong or too weak) binding energy toward H^+ ,²³⁻²⁴ the NiFe based materials still suffer from inferior HER activity;²⁵ hence the preparation of possible bifunctional NiFe-based catalysts for efficient OER and HER remains a challenge.

Here, we describe a lamellar $\text{FeNi}_3\text{-FeNi}_3\text{N}$ catalyst prepared using a facile hydrothermal method, followed by nitridation. The FeNi_3N nanospheres are in situ formed and dispersed rather well on the surface of lamella like FeNi_3 matrix during thermal nitridation. This gives rise to the formation of $\text{FeNi}_3\text{-FeNi}_3\text{N}$ heterostructures at the interface of FeNi_3N and FeNi_3 . Density functional theory (DFT) calculations indicate that some hollow sites that exist in $\text{FeNi}_3\text{-FeNi}_3\text{N}$ heterostructures show a lower Gibbs free energy for adsorbed atomic hydrogen, and therefore it contributes to high activity toward HER. Simultaneously, the FeNi_3N nanospheres enhance the number of accessible electrochemical active sites for OER, and hence dramatically increase the specific activity toward OER. For demonstrating practical use of $\text{FeNi}_3\text{-FeNi}_3\text{N}$ catalysts - both HER and OER are run in alkaline media within a symmetric alkaline water electrolyzer. The electrolyzer is assembled using efficient

FeNi₃-FeNi₃N as anodic and cathodic materials; the device displays a low overpotential with 1.5 V cell voltage at 10 mA cm⁻² current density.

Results and discussion

The lamella like FeNi₃-FeNi₃N is synthesized through a facile two-step strategy. As shown in **Figure 1a**; ferric nitrate and the nickel nitrate are first dissolved into the mixture of cis-9-octadecenylamine and butyl alcohol solvents to form a homogeneous solution. The collected NiFe hydroxide through hydrothermal treatment is then heat treated under ammonia flow to achieve nitridation.

The X-ray diffraction (XRD) pattern of the FeNi₃ in **Figure S1** matches well with that of FeNi₃ alloy (PDF#38-0419). In addition to the FeNi₃ alloy phase, cubic FeNi₃N (PDF#50-1434)^{15, 25} featured peaks at 41.52°, 48.34° and 70.81° are observed for the FeNi₃N-FeNi₃ sample annealed in ammonia at 460 °C (**Figure 1b**). The Rietveld refined result suggests the ratio of cubic FeNi₃N and FeNi₃ crystalline phase is 22:78. The XRD patterns of samples calcined at different temperatures are shown in **Figure S2**, and it clearly shows that FeNi₃ alloy would be gradually converted into FeNi₃N with the increase of temperature. When the nitriding temperature is increased to 650 °C, only pure phase of FeNi₃N is formed in **Figure S1**. The crystal structure is further confirmed by transmission electron microscopy (TEM). For FeNi₃ in **Figure S3b**, the lattice fringes with d-spacing of 0.18 and 0.20 nm correspond to the (200) and (111) plane of cubic FeNi₃. After nitridation at a relatively high temperature of 650 °C for 2 h, the observed lattice fringes in the sample show a d-spacing of 0.22 nm, which is attributed to the (111) plane of cubic FeNi₃N (**Figure S3d**). Correspondingly,

both FeNi₃ and FeNi₃N featured lattice fringes are clearly observed in TEM images for FeNi₃-FeNi₃N (**Figure 1d**). Their nano domains are adjacent with a discernible interface, clearly showing the formation of FeNi₃-FeNi₃N heterostructure.²⁶⁻²⁸ Investigated by scanning electron microscopy (SEM) in **Figure 1e** and **Figure S4**, similar to pristine FeNi₃ alloy, FeNi₃-FeNi₃N maintains a lamella like morphology. However, the aggregation driven by high temperature leads to the transformation of morphology to sphere for FeNi₃N.

Electrocatalytic activity of as-prepared catalysts for HER is evaluated in 1.0 M KOH using a typical three-electrode system. A high purity of graphite rod is used as the counter electrode. Commonly, the overpotential at current density of 10 mA cm⁻² (η_{10}) is taken as the reference for HER activity assessment. As shown in **Figure 2a**, the HER overpotential of FeNi₃-FeNi₃N (51 mV) is closed to the value for Pt/C (40 mV), which in turn is far better than that in case of FeNi₃N and FeNi₃ nanocatalysts. And the overpotential (η) observed at 20 and 100 mA cm⁻² is 86 mV and 215 mV respectively, which slightly higher than Pt/C (55 mV and 156 mV based on current densities). In the **Figure S5**, it can be seen that the performance of FeNi₃-FeNi₃N for HER decrease with increasing temperature, and the sample calcined at 460 °C is the best. Specifically, the HER overpotential (η) of FeNi₃-FeNi₃N outperforms many FeNi-based materials in **Table S1**. Correspondingly, the Tafel slope in **Figure 2b** of FeNi₃-FeNi₃N is 83 mV decade⁻¹, which suggests the Volmer- Heyrovsky mechanism as the HER pathway, in which the Heyrovsky process ($\text{H}_2\text{O} + \text{H}_{\text{ads}} + \text{e}^- \rightarrow \text{H}_2 + \text{OH}^-$) is the rate-determining step (RDS). Inversely, the higher Tafel slope of FeNi₃ (182 mV dec⁻¹)

and FeNi₃N (264 mV dec⁻¹) indicates that the Volmer reaction dominates the HER kinetics.

Electrochemical impedance spectroscopy (EIS) analysis is performed on at $\eta = 70$ mV. As depicted in **Figure S6** and **Table S2**, the semicircle of FeNi₃-FeNi₃N in Nyquist plots indicates a charge transfer resistance (R_{ct}) of 55.2 Ω , which is smaller than that of FeNi₃ (67.4 Ω) and FeNi₃N (238.4 Ω). The low R_{ct} reveals that FeNi₃-FeNi₃N exhibits fast charge transfer rates, consistent with the HER activity. As shown in **Figure S7**, the double-layer capacitance (C_{dl}) is tested by the cyclic voltammetry method at different scan rate. Based on this, the corresponding calculated result listed in **Table S2** suggests FeNi₃-FeNi₃N possesses the largest electrochemical active surface area (ECSA) of 7.1 m² g⁻¹_{cat}.

To assess the kinetic barriers involved in HER, we have studied the effect of temperature on the performance of the catalysts (**Figure 2d** and **Figure S8**). HER proceeds more rapidly at elevated temperatures, reflecting the exponential temperature dependence of the chemical rate constant. The Arrhenius plots at $\eta = 100$ mV for three different catalysts allow extraction of electrochemical activation energies (E_a). As shown in **Figure 2d**, FeNi₃-FeNi₃N exhibit an E_a of 55.9 kJ mol⁻¹, which is lower than that in case of FeNi₃ (83.1 kJ mol⁻¹) or FeNi₃N (154.3 kJ mol⁻¹). This result suggests the lowest apparent barrier for HER on FeNi₃-FeNi₃N heterostructures.

To better understand the reason for catalytic activity of FeNi₃N, FeNi₃ and FeNi₃-FeNi₃N heterostructure toward HER, density functional theory (DFT)

calculations are used for constructing the correlative theoretical models (**Figure S15-18**) and for calculating the free energy of H* ($\Delta G(H^*)$) on them (**Table S3-S5**). Generally, a site with moderate value of $|\Delta G(H^*)| \approx 0$ is most active for the HER.²⁹⁻³⁰ The most active sites for FeNi₃N, FeNi₃ and FeNi₃-FeNi₃N are portrayed in **Figure 2c**. As shown in **Figure 2e**, the corresponding Gibbs free energy diagram of HER reveal that the hollow sites H2 (Fe-Ni-Ni) and H3 (Ni-Ni-Ni) in FeNi₃-FeNi₃N possess the lowest $|\Delta G(H^*)|$ value of 0.01 and 0.07 eV, confirming relatively more favorable H* adsorption kinetics on FeNi₃-FeNi₃N heterostructures during the HER process. In order to identify the effect of FeNi₃-FeNi₃N interface on electronic structure, charge density difference is calculated (**Figure S19**). Yellow and blue areas represent charge density increase and reduction, respectively. The electrons transferred from FeNi₃N to FeNi₃ leads to make the yellow areas are more close to FeNi₃. The abundant charge accumulation on FeNi₃ leads to a higher catalytic activity for FeNi₃-FeNi₃N interface than pristine FeNi₃N or FeNi₃. The stability of the HER catalysts is investigated using chronoamperometric measurement at a current density of 10 mA cm⁻², continuously for 11 hours. As presented in **Figure S9**, FeNi₃-FeNi₃N shows an initial overpotential of 40 mV, which is same as that of the Pt/C electrode. And no appreciable increase in overpotential is observed in this time interval. While for Pt/C, there is an increase of 117 mV observed.

The OER polarization curves (**Figure 3a**) collected via negative scan in 1.0 M KOH, shows an apparent peak at 1.30-1.40 V for Ni containing samples. This peak could be assigned to reduction of Ni³⁺ to Ni²⁺. And the OER current appears earliest

at 1.44 V for FeNi₃-FeNi₃N. At the OER current density of 10 mA cm⁻², an overpotential of 260 mV is needed for FeNi₃-FeNi₃N. By comparison, it is 280 mV, 270 mV and 370 mV for FeNi₃, FeNi₃N and IrO₂, respectively. And in terms of the polarization curves in **Figure S10**, we can find the material calcined at 460°C is the most favorable for OER. The FeNi₃-FeNi₃N with heterostructure exhibit the smallest Tafel slope of 53 mV dec⁻¹ (**Figure S11**), clearly indicating faster reaction kinetics in this case.

It is commonly known that the NiOOH which is in-situ formed during OER offers active sites in case of NiFe-based materials.^{12, 19} Thus, in terms of the reduction peak of Ni³⁺/Ni²⁺, the accessible active sites of Ni can be quantified using turnover frequency (TOF) calculation.^{19, 22, 31} As shown in **Figure 3b**, the reduction peak at range from 1.3 to 1.4 V is assigned to Ni³⁺/Ni²⁺.¹⁶ Compared to FeNi₃ (0.185 mW cm⁻²) and FeNi₃N (0.368 mW cm⁻²), the largest peak area of 0.618 mW cm⁻² for FeNi₃-FeNi₃N indicates that the FeNi₃-FeNi₃N heterostructure improves the density of accessible Ni site. Furthermore, the highest TOF is achieved on FeNi₃-FeNi₃N, which indicates superior OER intrinsic activity of FeNi₃-FeNi₃N catalyst. As shown in **Figure 3c** and **Table S6**, at overpotential of 300 mV, the TOF of FeNi₃-FeNi₃N is 0.32 s⁻¹, which exceeds that of FeNi₃ (0.20 s⁻¹) and FeNi₃N (0.14 s⁻¹). In addition, as shown in **Figure S12**, a much lower R_{ct} on FeNi₃-FeNi₃N (7.0 Ω cm²) than that of FeNi₃ (16.6 Ω cm²) and FeNi₃N (18.8 Ω cm²) also indicates faster interfacial electron transfer kinetics between FeNi₃-FeNi₃N and electrolyte during oxygen evolution.

The OER durability for the prepared materials is evaluated via galvanostatic method at 10 mA cm^{-2} . As shown in **Figure S13**, the OER catalyzed on $\text{FeNi}_3\text{-FeNi}_3\text{N}$ exhibits a lowest initial potential of 260 mV. And during a 11 h test, the potential remained unchanged; this reveals a substantial durability of $\text{FeNi}_3\text{-FeNi}_3\text{N}$ for OER.

As shown in **Figure S14**, our $\text{FeNi}_3\text{-FeNi}_3\text{N}$ catalyst needs much lower overpotential at a current density of 10 mA cm^{-2} for both HER (40 mV) and OER (260 mV) in 1.0 M KOH. This is clearly desirable performance in comparison to other reported transition metal-based electrocatalysts. Considering that the $\text{FeNi}_3\text{-FeNi}_3\text{N}$ has exceptional HER and OER properties, we employed $\text{FeNi}_3\text{-FeNi}_3\text{N}$ modified nickel foam (NF) as the cathode and anode to fabricate a symmetric electrolyzer for overall water splitting.

Figure 4a depicts the polarization curve of water splitting. The $\text{FeNi}_3\text{-FeNi}_3\text{N/NF}$ exhibits excellent performance: only a 1.5 V cell voltage is needed to deliver a 10 mA cm^{-2} current density; this is much lower than most of reported values (**Figure 4b** and **Table S7**). The lower of cell voltage; the more efficient and less expensive would the water splitting be. For different current densities, the corresponding voltage is found to be consistent with the potential difference (ΔV) between HER and OER measured in a three-electrode system for $\text{FeNi}_3\text{-FeNi}_3\text{N}$ (**Figure 4c**).

The electrolyzer demonstrates good long-term catalytic durability, sustaining constant galvanostatic electrolysis for up to 48 h at a controllable current density (10 to 40 mA cm^{-2}) with negligible degradation (**Figure 4d**). This suggests excellent

potential for practical applications. The Faradaic efficiency (FE) of FeNi₃-FeNi₃N for the HER and OER is measured quantitatively from the total amount of charge passed through the cell during electrolysis and the total amount of evolved gas collected by water–gas displacement method.³² The amount of generated H₂ and O₂ matches well with the theoretically calculated amount under total charge during the electrolysis process (**Figure 4e**). This suggests that the FE is close to 100% for both HER and OER, with the ratio of H₂ and O₂ being close to 2:1.

Conclusions

We report that FeNi₃-FeNi₃N heterostructure offers excellent bifunctional catalytic performance towards HER and OER. This is due to the formation of highly active Fe-Ni-Ni and Ni-Ni-Ni hollow sites for HER and a large amount of electrochemically active sites available for OER on the FeNi₃-FeNi₃N heterostructure. The excellent HER and OER activities makes this catalyst suitable for both electrodes, and renders it directly relevant for overall water splitting. A demonstration electrolyzer exhibits a low driving voltage of 1.50 V at the current density of 10 mA cm⁻². Furthermore, the heterostructureelectrocatalyst exhibits remarkable activity with a negligible decay after 48h of operation.
