ABSTRACT

Melanoma is a malignant proliferative disease originated from melanocyte transformations, which are characterized by a high metastatic rate and mortality. Advances in Nanotechnology have provided useful new approaches and tools for antitumor chemotherapy. The aim of this study was to investigate the molecular mechanisms underlying chitosan nanoparticles containing S-nitroso-mercaptosuccinic acid (S-nitroso-MSA-CS)-induced cytotoxicity in melanoma cells. S-nitroso-MSA-CS induced concentration-dependent cell death against B16-F10 tumor cells, whereas non-nitroso nanoparticles (CS or MSA-CS) did not induce significant cytotoxicity. Additionally, melanoma cells were more sensitive to cell death than normal melanocytes. S-nitroso-MSA-CS-induced cytotoxicity exhibited features of caspase-dependent apoptosis and it was associated with oxidative stress, characterized by increased mitochondrial superoxide production and oxidation of protein thiol groups. In addition, tyrosine nitration and cysteine S-nitrosylation of amino acid residues in cellular proteins were observed. The potential use of these nanoparticles in antitumor chemotherapy of melanoma is discussed.

Keywords: Cytotoxicity, Melanoma, Nanoparticles, Nitric Oxide, S-nitrosothiol.

INTRODUCTION

1
2
3
4
5 Skin cancer is the most common type of cancer in Caucasian populations,^[1] and the
6
7 clinical classifications are based on the tumor origin and divided into non-melanoma skin
8
9 cancer and melanoma.^[2] Melanoma arises from cumulative abnormalities in melanocytes in
10
11 response to ultraviolet-induced DNA damage, resulting in genetic mutations that support their
12
13 malignancy through stimulation of blood vessel growth, evasion of the immune response and
14
15 apoptosis, tumor invasion and metastasis.^[3] Specific gene mutations are associated with an
16
17 increased risk of melanoma, e.g., the substitution of valine (V) to glutamic acid (E) at position
18
19 600 in the BRAF gene (BRAF V600E), which is reported in 40-50% of melanoma cases.^[4]
20
21

22
23 Early diagnosis of melanoma is crucial for the effectiveness of treatment and favorable
24
25 prognosis of patients. Available tools for melanoma treatment include surgical excision,
26
27 immunotherapy, radiotherapy, and chemotherapy.^[5] Immunotherapy (ipilimumab) or targeted
28
29 therapy (vemurafenib) are the main chemotherapeutic approaches used for the treatment of
30
31 metastatic melanoma when the BRAF V600E mutation is expressed.^[6] Antitumor drugs have
32
33 serious side effects, including hypotension, neutropenia, gastrointestinal and skin
34
35 dysfunctions, and hair loss.^[6] Specifically, for the treatment of melanoma, toxic side effects
36
37 described for vemurafenib include photosensitivity, follicular hyperkeratosis, maculopapular
38
39 rash, arthralgia, QT prolongation, and others.^[7] For ipilimumab, the most common side
40
41 effects described include diarrhea, nausea, constipation, abdominal pain, vomiting, vitiligo
42
43 and dermatitis,^[8] although more deleterious side effects had already been described such as
44
45 hepatitis,^[9] enterocolitis,^[10] pancreatitis and nephritis.^[11] New approaches are emerging in the
46
47 drug discovery field due to the recent advances in Nanotechnology, providing additional
48
49 opportunities to overcome drug resistance and toxicity, which are considered the major
50
51 limitations in melanoma chemotherapy.^[12] These nanotechnological strategies involve the
52
53 development of several types of nanostructured drug delivery systems focused on the
54
55
56
57
58
59
60

1
2
3 improvement of the specificity and efficacy of chemotherapeutic drugs, increasing the drug
4
5 concentration inside the tumor mass, and decreasing toxicity of chemotherapy.^[13]
6

7
8 Polymeric nanoparticles form colloidal systems, which are potentially useful for
9
10 carrying drugs with low water solubility and/or controlling drug release, providing increased
11
12 stability and drug delivery profile.^[14] Therefore, chitosan, which is a biocompatible, nontoxic,
13
14 and biodegradable polymer with pharmaceutical applications, has been widely used for
15
16 nanoparticle preparation.^[15] It is well known that nitric oxide (*NO) is involved in various
17
18 physiological cellular processes such as differentiation and apoptosis.^[16] At high
19
20 concentrations, *NO exhibit anticancer properties,^[17] however, due to its short half-life in
21
22 biological environments (1-5 s), it becomes difficult to reach these antitumor
23
24 concentrations.^[18] To increase their bioavailability and *in vivo* stability, low molecular weight
25
26 molecules capable of acting as *NO donors, such as S-nitrosothiols (RSNOs), have been
27
28 developed.^[19] Considering that *NO-releasing polymeric nanomaterials are emerging as a
29
30 promising strategy in cancer chemotherapy,^[20] biocompatible chitosan nanoparticles (CS)
31
32 were synthesized and used to encapsulate low molecular weight mercaptosuccinic acid
33
34 (MSA), a thiol-containing small molecule. Free thiol groups on mercaptosuccinic chitosan
35
36 nanoparticles (MSA-CS) were nitrosated to form S-nitroso-MSA-containing chitosan
37
38 nanoparticles (S-nitroso-MSA-CS). S-nitroso-MSA belongs to the class of RSNOs and acts as
39
40 a *NO donor. S-nitroso-MSA-CS was previously synthesized and characterized and had its
41
42 cytotoxicity screened in different cancer cells lines.^[21] Additionally, the transdermal *NO
43
44 delivery in human skin upon dermatological application of S-nitroso-MSA-CS was
45
46 demonstrated.^[22] Here, we investigated the underlying mechanisms of cytotoxicity of S-
47
48 nitroso-MSA-CS in an *in vitro* melanoma model.

EXPERIMENTAL SECTION

Synthesis of MSA-CS and nitrosation to produce S-nitroso-MSA-CS

CS nanoparticles were prepared using an ionotropic gelation process.^[23] Briefly, 0.1 g of CS was solubilized in 0.1 L of 1% acetic acid plus 66.7 mM MSA. Under magnetic stirring, 5.0 mL of 0.6 mg/mL sodium tripolyphosphate was added dropwise in 15 mL of MSA-CS suspension. The final mixture was stirred for 45 minutes at 25°C to form the aqueous suspension of CS (1.0 mg/L of CS) containing 7.5 mg/mL of MSA (which corresponds to 50 mM MSA). Control CS was prepared without the addition of MSA. The thiol groups of MSA-CS were nitrosated by reacting with an equimolar amount of sodium nitrite in acidified medium, as previous described.^[24] This solution was homogenized, protected from light, incubated for 30 min, and used immediately in experiments. The formation of S-nitroso-MSA-CS was confirmed by the detection of S-NO characteristic absorption bands at 336 and 545 nm.

Cell culture and standard incubation conditions with NPs

Cell line B16-F10 was purchased from the Rio de Janeiro Cell Bank (BCRJ 0046) (murine melanoma), and Melan-A (murine normal melanocytes) was generously provided by Prof. Miriam Galvonas Jasiulionis (UNIFESP) in 2015. Consequently, the authors performed no additional authentication. All cell lines were tested to be mycoplasma-free by indirect staining with Hoechst 33258 (Thermo Fisher Scientific, USA) and were used within 3 months of thawing the frozen stock. Cells were grown in DMEM (Dulbecco's Modified Eagle's medium) high glucose medium (Sigma-Aldrich, USA) pH 7.2, supplemented with 10% fetal bovine serum (Gibco, Invitrogen, USA), 100 U/mL penicillin and 100 µg/mL streptomycin, in a 5% CO₂ atmosphere at 37°C (Panasonic MCO-19AIC, Japan). For experiments, cells were

1
2 detached, centrifuged ($160\times g$ for 10 minutes), and suspended in supplemented DMEM
3 medium. B16-F10 cells (5.26×10^4 cells/cm²) were added to microplates for 24 h for cell
4 adhesion. After, S-nitroso-MSA-CS (20 and 40 $\mu\text{g/mL}$) was added and incubated for
5 additional 24 h.

7
8
9
10

11 12 13 **Cytotoxicity assays**

14
15 The cytotoxicity of NPs was screened by the trypan blue dye exclusion assay in B16-F10
16 melanoma cells and melanocytes Melan-A. Compounds were added at increasing
17 concentrations (5.0, 10, 20, and 40 $\mu\text{g/mL}$) and incubated for 24 h. After this, trypan blue was
18 added 0.016% (w/v) and cells were counted using a Neubauer chamber. Additionally, the
19 effects of modulators of cell death induced by S-nitroso-MSA-CS were evaluated by the MTT
20 reduction test. Thus, after an incubation period, 0.25 mg/mL MTT was added and incubated
21 for 4 h. Then, 0.1 mL of 10% SDS was added, incubated overnight, and plates were read at
22 570 nm/620 nm (Biochrom Asys Expert Plus Microplate Reader, Biochrom Ltd., UK). The
23 modulators [50 μM Boc-D-FMK (Sigma-Aldrich, USA), 5 μM MY5445 (Tocris Bioscience,
24 USA), 100 μM PTIO (Sigma-Aldrich, USA)] were pre-incubated 1 hour before the addition
25 of the nanoparticles. Cell viability in both assays was calculated in relation to the control
26 (absence of NPs), which was considered as 100%.

Annexin V-FITC/PI double staining flow cytometry analysis

After a standard incubation, cells were detached, centrifuged (160×g for 10 minutes) and suspended in 50 μL of binding buffer^[25] plus 5.0 μL Annexin V-FITC (BD Biosciences, USA) and 5.0 μL PI (BD Biosciences, USA). The mixture was incubated in the dark at room temperature for 20 minutes. After addition of 0.3 mL of binding buffer, fluorescence emission was measured with a FACSCanto II Flow Cytometer (BD Biosciences), acquiring 10,000 events per sample using a Coherent® Sapphire™ 488-20 solid state blue laser with an excitation at 488 nm, dichroic mirror 502 LP, bandpass filter 530/30 for the FITC fluorescence channel and dichroic mirror 556 LP, bandpass filter 585/42 for the PI fluorescence channel. Data analysis and graphs was completed using Flow Jo vX.0.7 software (Ashland, USA).

Active caspase 3

Caspase 3 was measured by flow cytometry using a monoclonal antibody against the active form. After a standard incubation, cells were fixed with 2% paraformaldehyde in PBS for 30 min and permeabilized with 0.01% saponin in PBS for 15 min at room temperature. Cells were then collected and incubated with 10 μL anti-active-caspase-3 monoclonal antibody conjugated with FITC #559565 (BD-Pharmingen, USA). After a 40-min incubation at 37 °C, the fluorescence emission was analyzed acquiring 10,000 events per sample using blue laser excitation (488 nm), dichroic mirror 502 LP, bandpass filter 530/30 and the FITC fluorescence channel with a FACSCanto II Flow Cytometer. Data analysis and graphs were completed using Flow Jo vX.0.7 software.

Reduced protein thiol content

1
2
3 Total protein –SH groups were quantified using 5,5'-dithiobis (2-nitrobenzoic) acid (DTNB).
4
5 After a standard incubation, cells were detached and centrifuged for 10 min at 700×g. The
6
7 pellet was treated with 0.2 ml of 6% trichloroacetic acid and centrifuged at 6000×g for 15 min
8
9 to precipitate the proteins. This precipitate was suspended with 1 ml of 0.5 M potassium
10
11 phosphate buffer pH 7.6 by vortexing. After the addition of 0.1 mM DTNB, absorbance was
12
13 determined at 412 nm (UV-Visible Spectrophotometer UV-1800, Shimadzu, Japan).
14
15
16
17

18 **Reactive oxygen species (ROS) production**

19
20 After a standard incubation, cells were collected and loaded with 5 μM MitoSOX™ Red or 5
21
22 μM CM-H₂DCFDA (Life Technologies, Invitrogen, USA) for 30 minutes. As positive
23
24 controls, 20 μM antimycin A and 100 μM hydrogen peroxide (H₂O₂) were used. End time
25
26 fluorescence emission was measured using the blue laser with an excitation at 488 nm,
27
28 dichroic mirror 502 LP, bandpass filter, 530/30 FITC fluorescence channel for CM-
29
30 H₂DCFDA and the dichroic mirror 556 LP, bandpass filter 585/42 for the PI fluorescence
31
32 channel for MitoSOX™ Red with a FACSCanto II Flow Cytometer. Data analysis and graphs
33
34 was completed using Flow Jo vX.0.7 software. Alternatively, continuous ROS production was
35
36 evaluated. After incubation with S-nitroso-MSA-CS for 2 h, cells were loaded with 5 μM
37
38 CM-H₂DCFDA for 30 min and fluorescence was kinetically recorded for 120 minutes in a
39
40 microplate reader Synergy HT (Biotek Instruments, USA) at 485 nm and 528 nm excitation
41
42 and emission, respectively. As positive control, 2 mM *t*-BOOH (Sigma-Aldrich, USA) was
43
44 used, and 100 U/mL PEGylated catalase (Sigma-Aldrich, USA) was used to distinguish the
45
46 fluorescence signal attributed exclusively to the peroxide production.

RESULTS

Enhanced and selective cytotoxicity of S-nitroso-MSA-CS in melanoma B16-F10 cells

The effects of S-nitroso-mercaptopropionic acid containing chitosan nanoparticles (S-nitroso-MSA-CS) (Fig. 1A) on B16-F10 and Melan-A cell viability were screened by the trypan blue exclusion assay. S-nitroso-MSA-CS exhibited high cytotoxicity against the B16-F10 tumor cell line in a concentration-dependent manner after 24 h of incubation. Such cytotoxicity was higher in tumor cells than in normal melanocytes (Fig. 1B). Additionally, non-nitroso MSA chitosan nanoparticles (MSA-CS), empty chitosan nanoparticles (CS), free S-nitroso-MSA, and MSA (in the same molar ratio used in Fig. 1B) were evaluated in B16-F10 cells and no significant cytotoxicity was achieved, showing the dependence of the nanoparticle structure (Fig. 1c). In flow cytometry, the frontal dispersion of the laser (forward scatter, FSC) gives information about the relative cell size and the lateral dispersion (side scatter, SSC) is related to granularity or complexity of the cell. S-nitroso-MSA-CS decreased cell size and increased the granularity of melanoma cells, defining a 'dead' population (Fig. 1D), which was dependent on concentration (Fig. 1E). Additionally, S-nitroso-MSA-CS induced the loss of normal morphology, membrane blebbing, cell shrinkage, emission of plasma membrane projections, and disruption. The loss of adhesion with the external matrix and neighboring cells was also observed (Fig. 1F).

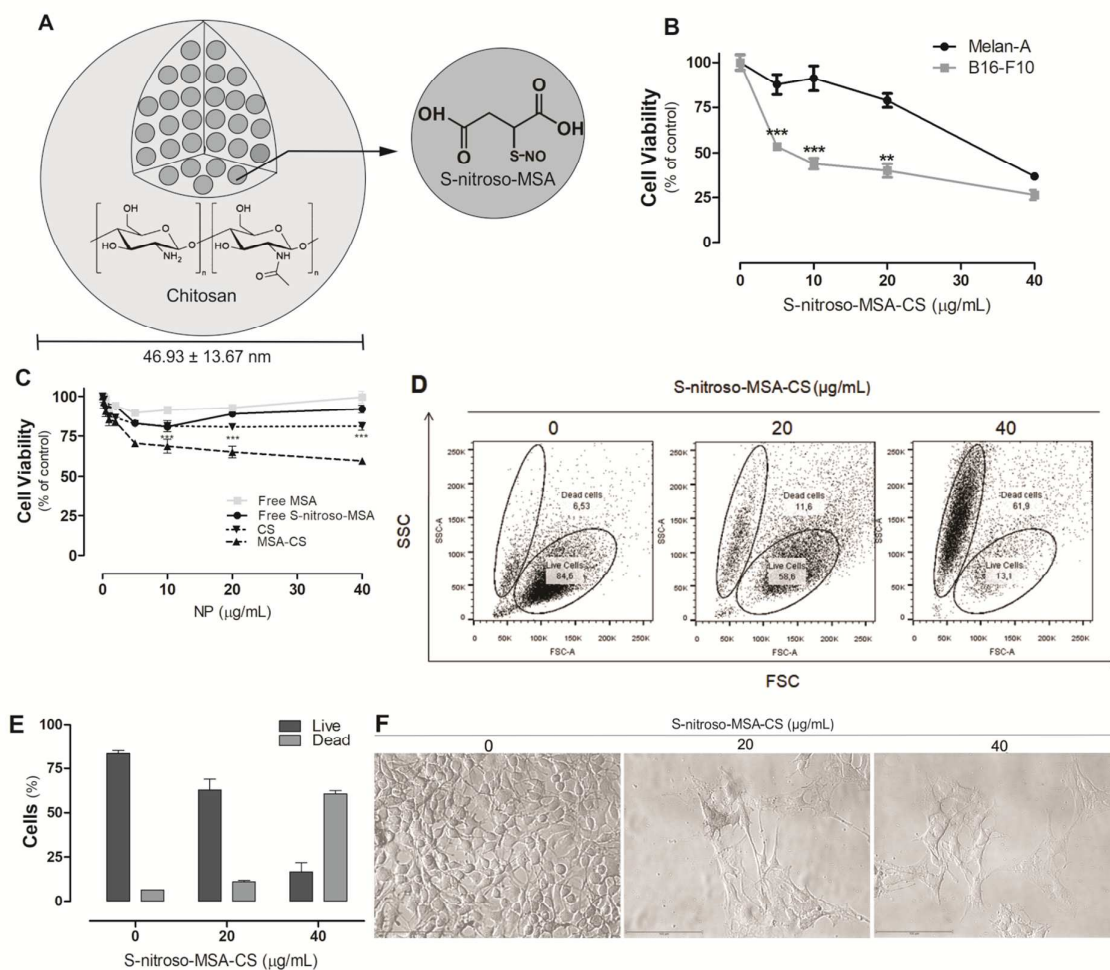

Fig. 1. Enhanced and selective cytotoxicity of S-nitroso-MSA-CS in melanoma B16-F10 cells. (A) Schematic representation of the S-nitroso-MSA-CS nanoparticle structure. (B) Effects of S-nitroso-MSA-CS on B16-F10 (gray line) and Melan-A (black line) cell viability assessed by trypan blue assay. ***($p < 0.001$) and **($p < 0.01$) indicates a difference from Melan-A at each concentration. The results presented as the mean \pm SEM of at least three independent experiments performed in triplicate. (C) Effects of MSA-CS (dashed line), CS (dotted line), free S-nitroso-MSA (black line), and free MSA (gray line) on B16-F10 cell viability. 12

13 14 **S-nitroso-MSA-CS induced apoptosis in melanoma cells**

15
16 To obtain a better understanding of S-nitroso-MSA-CS-induced cell death, molecular markers
17
18 of apoptosis and necrosis were evaluated. Annexin V-FITC/PI double staining flow cytometry
19
20 revealed the predominance of double stained B16-F10 cells (annexin V⁺/PI⁺), indicative of
21
22 late apoptosis (Fig. 2A). Since the dot plot graph is one representative experiment, the
23
24 quantification of apoptotic cells (annexin V⁺), considering all replicates was presented (Fig.
25
26 2B). Additionally, the activation of effector caspase 3 during S-nitroso-MSA-CS-induced cell
27
28 death was shown (Fig. 2C and 2D). The cell-permeable irreversible general caspase inhibitor
29
30 Boc-D-FMK also prevented cell death (Fig. 2E), corroborating the participation of caspases.
31
32 The pre-incubation of B16-F10 cells with necrostatin-1 (Sigma-Aldrich #N9037) and IM-54
33
34 (Sigma-Aldrich #SLM0412), inhibitors of necroptosis and necrosis, respectively, did not
35
36 prevent the S-nitroso-MSA-CS-induced cytotoxicity (Fig. 2F and 2G). In accordance, loss of
37
38 plasma membrane integrity induced by S-nitroso-MSA-CS was not observed, as evaluated
39
40 through the absence of LDH release by the cells (Fig. 2H). Thus, S-nitroso-MSA-CS induced
41
42 caspase-dependent apoptosis in melanoma cells.

18 **Increased oxidative stress induced by S-nitroso-MSA-CS**

19
20 A general view of the cellular reactive oxygen species (ROS) production can be achieved by
21 the assessment of oxidized dichlorofluorescein (DCF) fluorescence emission.^[26] Thus, B16-
22 F10 melanoma cells were incubated with S-nitroso-MSA-CS for 24 h and loaded with CM-
23 H₂DCFDA. As observed in Fig. 3A, S-nitroso-MSA-CS at 20 and 40 μ g/mL (dashed and
24 black lines, respectively) increased ROS generation in B16-F10 melanoma cells. Hydrogen
25 peroxide (H₂O₂) was used as a positive control (dotted line). The fluorescence quantification
26 of replicates is presented in Fig. 3B. Considering the relative lack of specificity of this
27 fluorophore to identify a specific free radical type, a kinetic measurement of ROS production
28 elicited by S-nitroso-MSA-CS (dashed lines) with CM-H₂DCFDA was performed for 120
29 minutes in the presence of catalase conjugated with polyethylene glycol (PEG-CAT, solid
30 lines) (Fig. 3C). The quantification of DCF fluorescence emission at 120 minutes revealed
31 that part of the DCF oxidation at 20 μ g/mL S-nitroso-MSA-CS was attributed to the peroxide
32 production but at 40 μ g/mL S-nitroso-MSA-CS PEG-CAT did not suppress the emission of
33 fluorescence (Fig. 3D), indicating that the radical production profile is different depending on
34 the NPs concentration. Since H₂O₂ can be formed by dismutation of superoxide anions
35 produced by mitochondria, we also evaluated the mitochondrial superoxide generation after a
36 24 h incubation with NPs using MitoSOX™ Red. As expected, S-nitroso-MSA-CS also

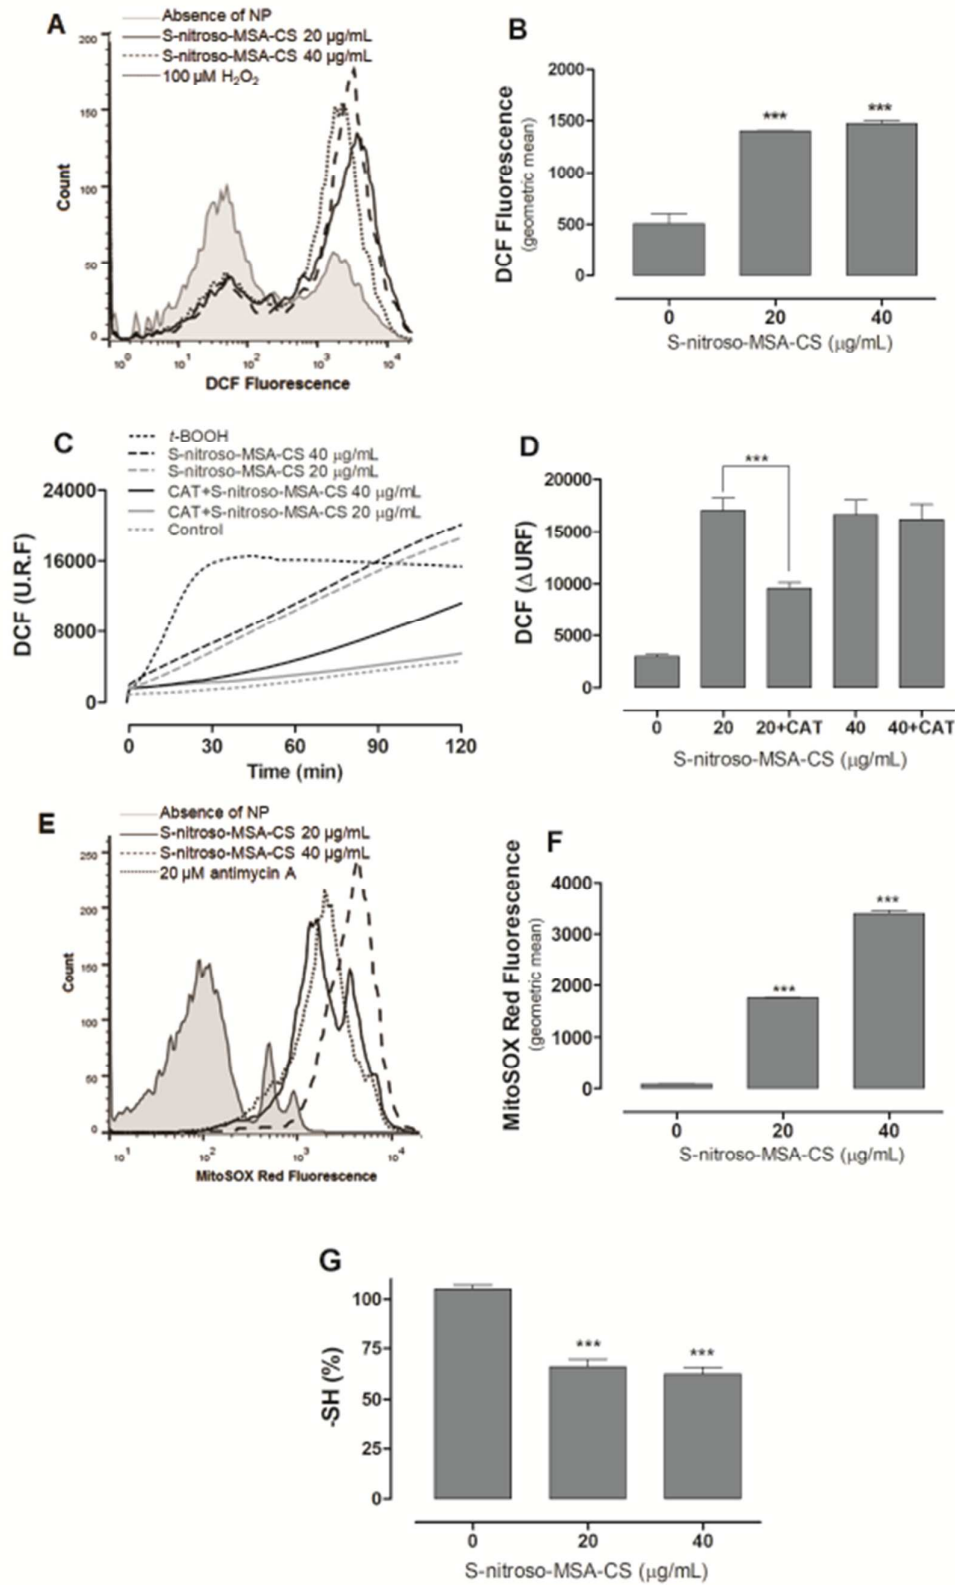

Fig. 3. Oxidative stress in B16-F10 melanoma cells exposed to S-nitroso-MSA-CS. (A)

Representative Histograms of DCF fluorescence obtained by flow cytometry. Gray line (absence of NPs), dotted black line (100 μM H_2O_2), black line (S-nitroso-MSA-CS 20 $\mu\text{g}/\text{mL}$), dashed black line (S-nitroso-MSA-CS 40 $\mu\text{g}/\text{mL}$). **(B)** Quantification of DCF fluorescence considering replicates. The results presented as the mean \pm SEM of at least three independent experiments performed in duplicate. ***($p < 0.001$) indicates a difference from control (absence of NPs). **(C)** Kinetic measurement of DCF fluorescence. Representative plot of DCFDA fluorescence intensity read at 120 minutes of at least two independent experiments performed in triplicate. **(D)** Quantification of DCF fluorescence from kinetics at $t=120$ minutes. ***($p < 0.001$) indicates a difference from control (absence of NPs). The results presented as the mean \pm SEM of at least two independent experiments performed in triplicate. **(E)** Representative histogramS of MitoSOX Red fluorescence obtained by flow cytometry. Gray line (absence of NPs), dotted black line (20 μM antimycin A), black line (S-nitroso-MSA-CS 20 $\mu\text{g}/\text{mL}$), dashed black line (S-nitroso-MSA-CS 40 $\mu\text{g}/\text{mL}$). **(F)** Quantification of MitoSOX Red fluorescence considering replicates. The results presented as the mean \pm SEM of at least three independent experiments performed in duplicate. ***($p < 0.001$) indicates a difference from control (absence of NPs). **(G)** Reduced thiol content in cellular proteins. The results presented as the mean \pm SEM of at least three independent experiments performed in triplicate. ***Different from control (absence of NPs) in panels B, F, and G.

Cysteine S-nitrosylation and tyrosine nitration promoted by S-nitroso-MSA-CS

The incubation of B16-F10 melanoma cells with S-nitroso-MSA-CS (20 and 40 $\mu\text{g}/\text{mL}$) resulted in an increased formation of 3-nitrotyrosine (Fig. 4A) and S-nitrosocysteine (Fig. 4B) in a concentration dependent manner. To evaluate whether these observed effects were due to $\cdot\text{NO}$ released by S-nitroso-MSA-CS, cells were pretreated with the $\cdot\text{NO}$ scavenger PTIO (Fig. 4C) and with an inhibitor of cyclic GMP phosphodiesterase MY5445 (Fig. 4D). Both

modulators were not able to change the cytotoxicity exerted by S-nitroso-MSA-CS, which provided strong evidence that the protein modifications were not promoted by free cytosolic $\cdot\text{NO}$ released from the nanoparticles.

Fig. 4. S-nitrosylation and tyrosine nitration of cellular proteins promoted by S-nitroso-MSA-CS. Indirect immunofluorescence with anti-nitrotyrosine (A) and anti-S-nitrosocysteine antibodies (B), with the respective quantification of fluorescence presented on right. Magnification 1000 \times , scale bars 50 μm . ***($p < 0.001$) indicates a difference from control (absence of NPs). Effects of 100 μM PTIO (C) and 5 μM MY5445 (D) on the S-nitroso-MSA-CS induced cytotoxicity. The results presented as the mean \pm SEM of at least three independent experiments performed in triplicate.

DISCUSSION

The cytotoxicity of $\cdot\text{NO}$ donors was described in different tumor cell lines, including ovarian cancer,^[28,29] lung carcinoma,^[30] breast adenocarcinoma,^[31] hepatocellular carcinoma^[32] neuroblastoma^[33] and squamous cell carcinoma of the head and neck.^[34] Such effects were associated with the inhibition of cell proliferation and induction of apoptosis.^[35] In B16-F10 melanoma cells, organic nitrate $\cdot\text{NO}$ donors inhibited their metastatic potential, and DETA/NO $\cdot\text{NO}$ donors reversed the resistance to chemotherapeutic agents, including doxorubicin.^[36] Additionally, organic nitrate $\cdot\text{NO}$ donors prevented the formation of melanoma cell lung nodes in a murine melanoma *in vivo* model.^[37] These reports suggest the therapeutic potential use of $\cdot\text{NO}$ donor nanomaterials in many types of cancer antitumor chemotherapy, including melanoma. Here, a nanostructured system containing $\cdot\text{NO}$ and S-nitroso-MSA-CS exhibited cytotoxicity against B16-F10 melanoma cells with no significant cytotoxicity in normal melanocytes.

The mechanisms of cell death elicited by $\cdot\text{NO}$ donors depend on several factors, such as cell type and tumor stage. Sustained $\cdot\text{NO}$ production could act as a pro-apoptotic signal by activating caspases^[38] through its effect on mitochondria^[39,40] or by upregulation of death receptor expression and their sensitization to death ligands, as Fas-L (Fas ligand), TRAIL (tumor necrosis factor-related apoptosis-inducing ligand) and TNF- α (tumor necrosis factor- α).^[41] Our data demonstrated that the cytotoxicity induced by S-nitroso-MSA-CS in melanoma cells is through caspase-dependent apoptosis.

It is well established that $\cdot\text{NO}$ stimulates the soluble guanylyl cyclase resulting in an increase of intracellular cGMP,^[42] whereas cGMP phosphodiesterase leads to a decrease.^[43] The cGMP phosphodiesterase inhibitor, MY-5445, increases the intracellular cGMP levels and thus mimics the $\cdot\text{NO}$ effect,^[44] but it did not alter the cytotoxicity of S-nitroso-MSA-CS, as well as the $\cdot\text{NO}$ scavenger PTIO, despite the detection of NO-protein adducts as discussed

1
2
3 below. These data suggest that these nanoparticles probably do not act as a $\cdot\text{NO}$ releasing
4
5 prodrug.

6
7 Reactions between $\cdot\text{NO}$ and $-\text{SH}$ groups of protein cysteine residues lead to S-
8
9 nitrosylation, which is an important and reversible post-translational modification able to
10
11 regulate the activity and function of many proteins and cellular processes.^[45] S-nitroso-MSA-
12
13 CS increased cysteine S-nitrosylation and tyrosine nitration in melanoma cells. Probably the
14
15 S-nitroso groups of S-nitroso-MSA-CS were transferred directly to free thiol groups of
16
17 proteins through S-(trans)nitrosylation. In agreement, the occurrence of S-(trans)nitrosylation
18
19 without release of free $\cdot\text{NO}$ by RSNOs was previously proposed.^[46]

20
21
22 It is well known that the oxidation of protein thiol groups in mitochondrial membranes
23
24 is related to mitochondrial permeabilization and release of pro-apoptotic proteins to the
25
26 cytosol, triggering cell death.^[47,48] S-nitrosylation induced by S-nitroso-MSA-CS in
27
28 melanoma cells was accompanied by oxidative stress characterized by H_2O_2 and
29
30 mitochondrial superoxide overproduction, and by nitration of cellular proteins. In this regard,
31
32 mitochondrial dysfunctions elicited by $\cdot\text{NO}$ donors associated with increased superoxide
33
34 production have been described.^[49] Additionally, ruthenium nitrosyl complexes inhibited
35
36 mitochondrial respiration in hepatocarcinoma cells, resulting in ATP depletion, ROS
37
38 production, and cell death.^[50] Increased superoxide production in mitochondria may occur due
39
40 to nitration and inactivation of manganese-dependent superoxide dismutase^[51] and/or
41
42 inhibition of the respiratory chain.^[52] These superoxide can react with $\cdot\text{NO}$ generating
43
44 peroxynitrite that nitrates $-\text{OH}$ groups in tyrosine residues irreversibly, and the adduct 3-
45
46 nitrotyrosine is widely used as a nitrosative stress marker.^[53]

47
48
49
50 In summary, we presented here the cytotoxic effects of S-nitroso-MSA-CS on B16-
51
52 F10 melanoma cells. Such effects were selective to tumor cells when compared to normal
53
54 melanocytes and dependent on the entire nanoparticle composition; only CS, free MSA or
55
56

1
2
3 free S-nitroso-MSA did not exhibit significant cytotoxicity. Additionally, the investigation of
4
5 molecular mechanisms of cytotoxicity revealed that S-nitroso-MSA-CS induced an apoptotic
6
7 cell death profile, dependent on caspase activation, and associated with a cellular and
8
9 mitochondrial oxidative stress. Together these results point to the potential use of S-nitroso-
10
11 MSA-CS as an antitumor chemotherapy of melanoma.
