Acta Crystallographica Section C: Crystal Structure Communications specializes in the rapid dissemination of high-quality studies of crystal and molecular structures of interest in fields such as chemistry, biochemistry, mineralogy, pharmacology, physics and materials science. The numerical and text descriptions of each structure are submitted to the journal electronically as a Crystallographic Information File (CIF) and are checked and typeset automatically prior to peer review. The journal is well known for its high standards of structural reliability and presentation. *Section C* publishes approximately 1000 structures per year; readers have access to an archive that includes high-quality structural data for over 10000 compounds.

(Received 27 August 1996; accepted 17 October 1996)

Abstract

The title compound, 1,3-bis[(*S*)-(-)-1-phenylethyl]thiourea, $C_{17}H_{20}N_2S$, exhibits bond lengths and angles consistent with the build-up of negative charge on the S atom. There are weak hydrogen bonds between molecules leading to helices disposed about crystallographic 3_1 axes.

Comment

Our recent interest in the application of guanidines as ligands for transition metals has lead us to isolate a number of different thiourea compounds as intermediates in their synthesis (Bailey, Blake, Kryszczuk, Parsons & Reed, 1995). We report here the crystal structure of one of these, namely, enantiomerically pure bis[(*S*)-(-)- α -methylbenzyl]thiourea, (1), which was synthesized *via* standard procedures from (*S*)-(-)- α -methylbenzylamine and carbon disulfide (Yamazaki, Higashi & Iguchi, 1974).

The crystal structure is composed of discrete molecules of (1) (Fig. 1), the bond lengths and angles (Table 1) being quite typical for acyclic thiourea compounds in the Cambridge Structural Database (Allen & Kennard, 1993; Fletcher, McMeeking & Parkin,

Fig. 1. A view of the title molecule with the atom-numbering scheme. Displacement ellipsoids enclose 30% probability surfaces. The dihedral angle between the planes of the phenyl rings is 11.6 (4)°.

1996). The C—S bond length [1.710 (7) Å] lies at the low end of the range associated with C—S single bonds (1.70–1.80 Å; Allen, Kennard, Watson, Brammer, Orpen & Taylor, 1992), while the average C—N bond length [1.321 (8) Å] is similar to 'standard' C—N bonds in aromatic rings [1.336 (14) Å; Allen *et al.*, 1992]. Compound (1) should thus be properly regarded as a resonance hybrid of C=N-containing canonical forms, with only a relatively small contribution from the C=S-bonded form frequently used to represent thiourea compounds (see scheme below). The phenyl groups adopt a pseudo-antiperiplanar arrangement in order to minimize steric crowding of the α -methylbenzyl functionality.

Hydrogen bonds link molecules to form a helix around the crystallographic threefold screw axis. Each molecule is linked to its neighbour in the helix by two N—H...S interactions [N1A...Sⁱ 3.411 (6) and N1B...Sⁱ 3.545 (7) Å; symmetry code: (i) 2 - y, 1 + x - y, $\frac{1}{3}$ + z]. There appear to be no significant contacts between the helices.

Experimental

Crystals of (1) were grown from dichloromethane layered with diethyl ether. At 1.08 mm, the crystal selected for study is long by normal standards, but the crystals shattered when attempts were made to cut them. A 1.2 mm diameter collimator was used during data collection.

Abstract

The crystal structure analyses of the title substituted *p*-terphenyls, 2'-(*p*-methoxyphenyl)-3'-phenyl-*p*-terphenyl, C₃₁H₂₄O, and 2',3'-bis(*p*-methoxyphenyl)-*p*-

Table 1. Selected geometric parameters ($\text{\AA}$, $^\circ$)

S—C	1.710 (7)	N1A—C2A	1.444 (8)
C—N1A	1.318 (8)	N1B—C2B	1.446 (8)
C—N1B	1.324 (7)		
N1A—C—N1B	115.5 (6)	C—N1A—C2A	127.3 (6)
N1A—C—S	121.4 (5)	C—N1B—C2B	128.7 (7)
N1B—C—S	123.1 (6)		

The crystal diffracted only weakly at high angle, so data were not collected beyond $\theta = 22.5^\circ$. H atoms attached to C atoms were placed in calculated positions and subsequently allowed to ride on their parent atoms with $U_{\text{iso}}(\text{H}) = 1.2U_{\text{eq}}(\text{C})$. Methyl groups were treated as rotating rigid groups with $U_{\text{iso}}(\text{H}) = 1.5U_{\text{eq}}(\text{C})$. H atoms attached to N atoms were located in a difference synthesis; the positional parameters were refined subject to similarity restraints on the N—H distances and the isotropic displacement parameters refined freely.
