Big data: Lessons for employers and employees

Abstract

Purpose: The focus of the current article is to critically reflect on the pros and cons of using employee information in big data projects.

Approach: The authors reviewed papers in the area of big data that have immediate repercussions for the experiences of employees and employers.

Findings: The review of papers to date suggests that big data lessons based on employee data are still a relatively unknown area of employment literature. Particular attention is paid to discussion of employee rights, ethics, expectations, and the implications employer conduct has on employment relationships and prospective benefits of big data analytics at work for work.

Originality/value: This viewpoint article highlights the need for more discussion between employees and employers about the collection, use, storage and ownership of data in the workplace. A number of recommendations are put forward to support future data collection efforts in organisations.

Keywords

big data; consent; data analytics; employment; education; ethics

Introduction

Computer and internet-based technology has steadily advanced in recent decades and changed working lives, both positively (e.g., working flexibly, remotely and virtually) and negatively (e.g., work intensification, 24/7 availability). These technological developments are the source of a dramatic increase in the amount and availability of data in the world (McAfee and Brynjolfsson 2012). Larger sets of data can be captured more readily than ever before, increasing the potential for developing analytical formulae and rules to solve problems (via algorithms to process data), which in turn generate insights in the form of new information processing or decision-making aids (Dormehl 2014).

Big data has become a popular label for many data analytics efforts. Originally, the term big data emerged to define the technological revolution that enabled immense data collection (Jacobs 2009). Since then, the term has migrated into other domains and stands for different analytical aspects, depending on the context within which big data is mentioned. The term is now used to refer to both data processing capabilities and the characteristics of data, encapsulating both technical but also commercial aspects of data collection activities (Nunan and Di Domenico 2017). Mayer-Schönberger and Cukier (2013) consider big data as the emerging ability to crunch vast collections of information and analyse it instantly (see also Kitchin 2014). In a similar vein, boyd and Crawford (2012, pg. 663) suggest that big data is not necessarily a statement describing the size of data but instead a term that designates the “capacity to search, aggregate, and cross-reference large data sets.”

The most important characteristic is the fact that big data analytics will go beyond traditional data sources (Ducey et al. 2015). Specifically, big data may involve several conjoined datasets from very different sources, and include data points generated from a variety of multimedia sources, such as video and audio records, pictures, different types of file formats captured presentations and texts, as well as sensors, frequencies, and behavioural traces such as

1
2
3 clickstreams on websites (Zikopoulos et al. 2012). Within organisations, much of the
4
5 employee-focused data may be gleaned from their use of social learning and collaboration tools
6
7 on corporate intranets and social media platforms (Ducey et al. 2015). Many human resource
8
9 information systems (HRIS) are data-rich repositories of information about employees,
10
11 workplace events and conditions (Guzzo et al. 2015).
12
13

14
15 From a human resources (HR) perspective, big data represents a significant journey replete
16
17 with opportunities and challenges. These include identifying and demonstrating novel sources
18
19 of workforce value, evidence, and impact in ways not possible before, when HR was a back-
20
21 office function, relatively untouched by strategic digital transformation and data revolution.
22
23 Accordingly, the Chartered Institute of Personnel and Development (CIPD), a leading
24
25 association for the HR profession in the UK, has produced a suite of reports and resources on
26
27 big data, people analytics, talent analytics and related topics (e.g. CIPD 2013, 2017, 2018a,
28
29 2018b).
30
31

32
33 Big data is related to many ongoing issues and conditions to support its use. These include
34
35 closing skills gaps, breaking out of silos to collaborate across the organisation, engaging with
36
37 senior executive governance and decision-making, developing human capital metrics and data
38
39 reporting standards, assessing people risks, positive relations of analytics cultures with
40
41 business performance, and variable international adoption levels. Some commentators assert
42
43 that small teams working on HR analytics are working through management cycles in various
44
45 industries, like IT, aviation, and retail. After two or three years of having more data
46
47 infrastructure and ecosystems in place, they can move past a 'honeymoon period' of initial
48
49 learning toward the next stage of maturity in problem-solving with big data (Belizon 2019;
50
51 Creelman 2019).
52

Pros and cons of big data for employers

At an organisational level, big data tools enable organisations to catalogue more personal communications than ever before, encompassing the views, sentiments, and behaviours of all those who interact with the organisational systems and interfaces, including employees (Lohr 2015). Big data has also allowed organisations to make improvements to existing processes (Nunan and Di Domenico 2017), often in the form of incremental progressions rather than significant reinventions. As with previous process improvement tools, the value of these small improvements cannot be underestimated, and the cost savings via improved organisational effectiveness can be significant. For example, organisations like Wal-Mart and Credit Suisse are using analytics to save turnover and churn costs by understanding who might quit the workforce and why, before they do so, saving millions a year where managers used the information anonymously to improve employee retention (Silverman and Waller 2015).

Nonetheless, there are persistent concerns revolving around poor data quality, and accountability, especially since employees are often active contributors to big data in organisations. Organisational accountability can remain unclear in relation to roles involved with keeping, processing, and analysing the data. In addition, many employees and managers may not agree with the extent to which employers seek confirmation in data rather than from employees themselves, increasing employee-focused data collection, but in the form of technological determinism rather than employee voice, and fostering the continuous quantification of HR practices. This argument is in line with concerns that data-driven modelling may also threaten the human agency associated with creativity, autonomy and self-determination (Dormehl 2014).

However, such concerns equally do not rule out potential opportunities for big data, AI models, and algorithms to take over mundane, repetitive tasks and free up and release more space and resources for employees to develop their soft skills and creativity in self-determining

1
2
3 ways (Wilson et al. 2017). Using data systems to support real-time employee self-service and
4
5 full integration and automation of leave, attendance, learning and performance development is
6
7 another way of envisaging this.
8
9

10 Many of these data-driven tensions will involve working through the changes in terms of
11
12 crucial constellations of organisational power (e.g. between union members and employers),
13
14 workforce diversity, and access to employment (e.g. where big data is used to profile job
15
16 candidates; Tonidandel et al. 2016). In the present manuscript, we focus mainly on new
17
18 questions that arise for professionals tasked with big data analytics, evaluation and evidence-
19
20 based implementation of findings of big data based on organisational (and specifically
21
22 employee) records.
23

25
26
27

28 **New data challenges for employers in the age of big data**

29
30 Employers today are not only able to monitor employee activities on their computers and
31
32 intranet but can also monitor their Internet activities via different devices, app activity,
33
34 keystroke logging and other ‘digital exhaust’ (Harford 2014). They are also able to monitor
35
36 employees during their offsite activities via their mobile devices, network traffic, and wearable
37
38 devices (many of which employers will provide at no cost to their employees). In recent years,
39
40 several researchers have started to identify ethics – in addition to privacy – as a major
41
42 consideration in terms of how big data are generated, used, analysed and interpreted more
43
44 generally (Gil de Zuniga and Diehl 2017). The following section will outline and discuss data-
45
46 specific challenges as well as employee-related issues.
47
48
49
50
51
52

53 ***Quality, quantity and use***

54
55 One of the key promises of big data is the knowledge that may be gained from it. While more
56
57 data may not straightforwardly translate into larger amounts of better quality data, big data can
58
59
60

1
2
3 mean improved access to good data or at least the existence of data where none previously
4 existed (Stone et al. 2018). Whatever the merits of particular data, findings will be partly
5 determined as they emerge from the positive and negative qualities of that data.
6
7
8

9
10 When more suboptimal, incomplete or poorer quality data are used, we can expect there to
11 be problematic implications for the conclusions drawn. Overall, big data tends to be more
12 unstructured than structured (Nunan and Di Domenico 2017), and a number of HR, Industrial-
13 Organisational (I-O) psychologists and critical data scholars have expressed reservations about
14 big data, emphasising recommendations for improving analytic practices (Angrave et al. 2016;
15 boyd and Crawford 2012; Guzzo et al. 2015; Kitchin 2014). Metrics therefore need to be clearly
16 defined and used uniformly in organisations, minimising and acknowledging essential details
17 or qualifications left out (Lytle 2016; Roberts 2013). Analytics and algorithms will only be as
18 good as the data put into them. Considerable time should be invested to evaluate and develop
19 new algorithms with care (Arnaout 2012), in order to incorporate the work context within their
20 metrics and analytic rules.
21
22
23
24
25
26
27
28
29
30
31
32
33

34
35 Data will vary in how fully they capture the information necessary to answer all employers'
36 questions. First, some problem-solving may focus on issues that are the symptoms of, but not
37 the origins or root causes of the presenting issue. Many workplace issues or problems
38 underlying employment relations are multi-dimensional, comprised of elements that are
39 difficult to model, even in big data, as these dimensions may be less tangible or unobservable
40 in the workplace (e.g. psychological climates at work). This is where suboptimal or poor quality
41 data can become a hurdle, in that it can provide some answers that an employer seeks, but will
42 still be unlikely to tell a manager how to tackle specific employee, team and work process
43 issues. As the metaphorical data 'haystack' containing the valuable needles - or insights -
44 becomes more substantial, this merely increases the likelihood of identifying spurious trends
45 (Aradau and Blanke 2015). Big data should therefore be carefully translated into meaningful
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 action plans that could be utilised in the improvement of employment practices (Toterhi 2014).
4
5 For example, Rasmussen and Ulrich's (2015) vignette detailed how Maersk drilling, an
6 offshore drilling organisation, used data analytics to optimise employee performance, but only
7
8 through a careful questioning and testing process relating links between team competence, error
9
10 types, leadership quality and customer satisfaction.
11
12
13

14
15 Ultimately, the imperfect quality and quantity of big data can therefore be offset to some
16
17 extent by more positive interpretive capabilities in how it is used by employers and employees
18
19 (Calvard 2016). At the negative extreme, big data usage could involve mindless, careless,
20
21 uninformed analyses that are more superficial and spurious in leading to adverse consequences.
22
23 However, under more positive organisational conditions, big data could be used diligently and
24
25 responsibly to make sense of complex phenomena from a range of perspectives.
26
27
28
29

30 ***Data storage and ownership***

31
32
33 There are also methodological data storage and analytical challenges facing employers
34
35 attempting to make sense of big data. Ducey et al. (2015, pg. 557) summarise this situation as
36
37 follows: "Big data is not just about a large data set, it is asking us to filter petabytes of data per
38
39 second from almost any connected device, analysing the data while still in motion, deciding
40
41 what if any data must be stored, and even using analytics tools to virtually integrate the data
42
43 with data stored in traditional warehouses." Additional challenges for employers involve the
44
45 retrieval, storage, security and archival requirements for employee data – addressing these will
46
47 often generate costs and require new procedures (Ducey et al. 2015).
48
49
50

51
52 Outsourcing data services to third-party vendors will change the dynamics of how
53
54 employers share responsibilities for data analytics storage and ownership, as well as the sharing
55
56 of resource-intensive data integration and conversion costs. External data analytics providers
57
58 cannot entirely reduce employers' legal responsibilities towards safeguarding employee data.
59
60

1
2
3 As a professional function, HR therefore sits at the centre of a greater variety of data sources,
4
5 but without having as much direct control over them. HR may be able to access some employee
6
7 data from its own banks (e.g., payroll), but these sources may not be straightforwardly linked
8
9 to other enterprise systems (Roberts 2013). Resolving these tensions through careful
10
11 collaboration will support connecting internal datasets to external datasets, such as those made
12
13 available by government agencies, as well as datasets containing industry benchmarks and
14
15 workforce demographics (Roberts 2013). Much depends on the favourability of national
16
17 conditions and the supply chain or stakeholder environment. Government and public sector big
18
19 data use cases show many possibilities for strong partnerships; for example, weather patterns,
20
21 law enforcement, health services, and regulatory compliance datasets are all publicly stored
22
23 and could be used to solve workforce-related problems affecting productivity and well-being.

57
58
59
60
There will always be some risk of ambiguity or lack of shared responsibility for addressing
the threats and fallout related to big data and data accidents (Nunan and Di Domenico, 2017).
Right now, many stakeholders may not feel they have a stake in managing risks unless they
have some personal stake in the data or have been directly affected by privacy violations.
Becker and Smidt (2016) raise the point that exposure to risk requires that the parties involved
actually have an interest in the outcome. Encouraging ownership of data but also the risks that
arise from it will be vital to increasing accountability and forward thinking. Strategies for
proactive accident handling and sector-wide knowledge sharing will also be needed for
instances when accidents inevitably occur.

Ethics and employee data: A continuing debate

Employee monitoring is far from a new phenomenon in the world of work (Karim et al. 2015).
However, the integration of data on a big data scale, and its use in predictive modelling, far
exceeds previous analytical capabilities. We consider the ethical challenges facing

1
2
3 organisations who use employee (big) data. In the age of big data, three central issues are at
4 the forefront of concern: consent, different privacy expectations, and the lack of guidance for
5 those tasked with data collection and analysis. We will discuss each of these briefly in turn.
6
7
8
9

10 11 12 *Employees as data contributors*

13
14 To date, data analytics, particularly big data analytics, raises new questions for how we respond
15 to a situation where employees are themselves contributors to a multitude of interconnected
16 datasets generated at work and away from work privately. Their role in generating this data
17 raises critical questions regarding the treatment of employees as information sources and
18 instruments in relation to data and algorithms. Other questions arise in terms of how employee
19 interests in the employment relationship are being served or exploited, and how their actions
20 are informing predictions about the future, predictions that may often be self-fulfilling. A
21 related issue concerns data privacy and protection expectations that employees hold in regard
22 to their employers, and how these may shape their acceptance or rejection of organisational
23 data collection efforts. Some employees will react more positively than others to the prospect
24 of carrying wearable devices provided by their employers, particularly invasive devices that
25 register physiological responses, physical mobility, and attributes of vocalization (Guzzo et al.
26 2015). This brings us to several key points.
27
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43

44 While consent may be a desirable and valuable component to any data collection effort, it
45 is only likely to be a requirement in certain circumscribed situations involving designated study
46 designs, participants, and research guidelines. When it comes to many other situations, such as
47 the use of archival data or blind anonymous surveys, consent is less likely to be an explicit
48 requirement. In the case of big data and workforce analytics, it would seem worthwhile to take
49 a more careful look at the value of consent and informed consent where none may be explicitly
50 required or expected – as is often the case over social media (Lam 2016). This is important
51
52
53
54
55
56
57
58
59
60

1
2
3 given that employees are often unwilling participants in data collection efforts when the
4 employer monitors their activities both on and off the job. The degree to which employees are
5 aware of how their data was acquired and tracked by organisations (e.g., via cookies; Peacock
6 2014) often varies, with some more aware than others. In addition, any employee working
7 online may not have wittingly given their informed consent to have their data used for
8 organisational data analytics.

Consent thus remains a key concern with employee data, particularly if organisations assume that they have consent without necessarily ensuring for certain that consent has indeed been given in an informed, verified, and ongoing way (Custers 2016). In line with informed consent, users should be able to easily understand exactly which data they have given their consent to being collected and to obtain verification information when consent has been denied or annulled. However, in the case of big data, this will be extremely challenging to ensure in practice, given the complexity of changing patterns of consent into the data, and the potential use of anonymised data following the expiry of consent (Custers 2016).

Data triangulation poses similar dilemmas to consent. Triangulation is an inherent part of big data's 'big' appeal, reflecting valuable opportunities to verify and cross-validate insights across larger and more various sets of sources of data (Nunan and Di Domenico 2013). However, the risk of removing individuals' anonymity needs to be managed, where triangulated data connects information in ways allowing identification. This should require individuals' acknowledgement or permission to share, particularly if being used to make decisions affecting their situation (George et al. 2014).

In many cases, there are the data sets generated by employees due to their use of multiple tools and platforms. In essence, an employee contributes to multiple datasets simultaneously, a phenomenon that creates ideal conditions for triangulation. At present, however, employment laws do not consider the implications and threats that arise due to big data triangulation, so

1
2
3 there are no safeguards in place to regulate triangulation, intentional or accidental. Similarly,
4
5 methods of data analysis have emerged that allow employers to de-anonymize data sets. One
6
7 such method is machine learning, a method that supports the automated analysis of analytical
8
9 models and model building. New analytical tools such as these now allow employers to profile
10
11 and identify individuals using social network information and HR details (Hashimoto et al.
12
13 2016).
14
15

16
17 A critical issue going forward is therefore to identify ways in which employers will ensure
18
19 adequate levels of personal data control, supporting appropriate levels of self-determination
20
21 and employee rights in the workplace. It is important to acknowledge that some big data
22
23 projects can be experienced very positively by the workforce if they are democratically and
24
25 transparently owned by the employees and used to further their own development. One such
26
27 example is Google's project 'Oxygen' (Garvin 2013). Here, the software engineering
28
29 workforce reported that using analytics to identify optimal management behaviours – as crucial
30
31 as breathing oxygen, hence the name – was extremely positive and valuable because the data
32
33 was 'about us, by us, and for us.'
34
35
36
37
38
39

40 ***Context still matters, even with big data***

41
42 Big data analytics represent an opportunity for a more far-reaching analysis of employment
43
44 contexts if the data is richer in quality and more thorough in its representation of a problem or
45
46 phenomenon. However, these analytics also risk fostering greater complacency in neglecting
47
48 the nuances of employment contexts if partial data is considered too readily to fully explain the
49
50 context or trivialise its role (Johns 2018).
51
52

53
54 For instance, at present, most algorithms can only predict well-defined, short-term outcomes
55
56 (Luca et al., 2016). Under conditions of uncertainty, and in the longer-term, such predictions
57
58 may not be robust enough to warrant the trust placed in them. While longitudinal data collection
59
60

1
2
3 (e.g. via live-streamed data) and analyses are increasingly possible, these are very resource-
4
5 intensive to maintain and process, reducing incentives to contextualise analytics temporally.
6
7 Importantly though, much of employee behaviour is a function of the employee's engagement
8
9 with their contextual environment, at levels ranging from the general through to the more
10
11 specific and local.
12
13

14
15 Furthermore, employees also engage in personal interactions with others in and outside the
16
17 workplace, settings which may be far less predictable or controllable, and introduce
18
19 unmeasured contextual variations and qualifications to prevailing interpretations. Advocates of
20
21 big data analytics may assume that employees and their behaviour are observable, with fixed
22
23 and highly generalisable characteristics. These assumptions of abstraction, reduction, and
24
25 essentialism of context have implications for employees. Employees could be labelled by data
26
27 (e.g. as opinion leaders or followers), for instance, given that past performance data is being
28
29 used to semi-permanently label them as poor, average, or good performers, independent of
30
31 other contextual factors, and outside of the original context of measurement. This
32
33 categorisation may affect their inclusion in and access to future training and development
34
35 opportunities.
36
37
38
39

40
41 The value of big data for employees lies in ensuring that it can provide or support more
42
43 holistic, nuanced understandings of themselves and the practices undertaken in the context of
44
45 their work. Big data decision-making therefore needs to be gradually embedded in governable
46
47 routines in ways that do not sacrifice contextualisation by literally taking data-driven employee
48
49 judgments too far 'out of context' (Janssen et al. 2017). One way to better take social context
50
51 into account, for instance, is to use *relational analytics* that focus more on relationships
52
53 between employees (influence, team networks, back-up support) instead of individual
54
55 attributes in isolation. Most companies, with clear policies in place, can contextualise their
56
57 analytics by collecting behavioural data from 'digital exhaust' – the emails, posts, logs, team
58
59
60

1
2
3 formations, and project milestones recorded by digital applications and platforms (Leonardi
4 and Contractor 2018).

10 **Recommendations**

11
12 In this section, we present several recommendations, not only for employers, but also for
13 employees. We focus on improving ethically responsible conduct and education in order to
14 avoid and recognise ethical workplace dilemmas, and the role of employers in improving
15 systems design to respect privacy. We hope that our recommendations provide informative
16 starting points for those tasked with managing the challenges for both employer and employees
17 in the process of creating new data projects related to big data efforts.

23
24
25
26
27

28 *Ethical data management via Chief Data/Information Officers*

29
30 As implied above, ownership of or responsibility for data can remain elusive, for both the data
31 analysts and the originators or subjects. This may be due to a lack of understanding by the data-
32 generating users of what data is generated and who owns it (Foster 2014). Similarly, big data
33 is often collected “regardless of, and potentially without knowledge of, the purpose for which
34 it is to be finally used” (Nunan and Di Domenico 2017, p. 487). Levels of responsibility,
35 accountability and awareness relate also to the recurrent expiration of licenses, products, and
36 software updates that are run and abandoned in rapid-release cycles (Clark et al. 2014). In
37 addition, the context surrounding how data are collected and analysed needs to be explored to
38 reduce uncertainty over how these sets of data are being used (Nunan and Di Domenico 2017).
39
40 These circumstances obfuscate the inherent privacy risks for the users who contribute to the
41 data.

46
47
48
49
50
51
52
53

54
55
56 One option to counteract such situations is to create organisational (data) ethics boards
57 (Medland 2016), or a similar kind of committee which would include chief data officers,
58
59
60

1
2
3 employee and union representatives, where appropriate. In particular, functions like HR, legal
4 compliance, and marketing will be increasingly likely to work closely together on establishing
5 revamped data protection roles and responsibilities, such as chief data privacy officers with
6 distinct expertise and independent decision-making powers (Smith, 2018). One example
7 concerns how Google has attempted to set up an eight-person AI ethics board, called the
8 Advanced Technology External Advisory Council, to ensure technology and data are ethically
9 developed. It has had to scrap it within a week of its announcement, however, due to employee
10 backlash over the political backgrounds and views of some of those appointed, highlighting the
11 important of diverse employee representation in ethical data management initiatives (Price and
12 Bastone 2019).

These issues now have increasing, wider relevance for many medium-sized and larger organisations that generate, use and analyse large datasets (or pay third parties to do so on their behalf). Good ethical practice and rigorous data security play an essential role in securing trust in organisations and strengthening their employee and stakeholder data management (e.g. Carucci 2016; Fung 2015). Analytics and algorithms can never achieve true 'objectivity', so it is important to challenge any strong truth-claims in organisational culture and management where appropriate (Aradau and Blanke 2015). In addition, such ethics boards or committees can identify when and where an employer should take steps to respect employee privacy and expectations in order to maintain productive and positive employment relationships. These boards may also include data scientists tasked with analysing big data sets (including data points collected from employees), and external experts to guide the process, in approaches similar to those used by research institutions to manage ethical research questions.

Ethics education for employers and employees

1
2
3 Analysts coming from the field of marketing, HR, or information systems are not necessarily
4 trained in ethics, nor are they familiar with basic ethical procedures behind data collection.
5
6 Many professionals who are asked to work with employee data are therefore facing a steep
7
8 learning curve about ethics, as well as a lack of organisational incentives to encourage such
9
10 engagement. Education, training, learning and development can together provide a means by
11
12 which employers become more cognizant of the ethics of using big data. Exactly how
13
14 employers decide to educate managers, employees and other stakeholders (e.g. union members)
15
16 about their data efforts may be subject to particular organisational requirements and data use.
17
18 However, what is key will be to establish ethical data management (as part of ethical leadership
19
20 in the workplace or via the establishment of ethics boards).
21
22
23
24
25

26 While it is important to recognise the learning and development responsibilities of
27
28 employers in setting ethical data analytics agendas from the top, the bottom-up responsibilities
29
30 and ethical training needs of employees as users should be emphasised too. Individuals and
31
32 collectives in the workplace have a more devolved responsibility to some extent for how they
33
34 access and curate sensitive data in their roles, in managing their own health and well-being, for
35
36 example (Moore and Piwek 2017). Employees should be widely encouraged to reflect on how
37
38 they deploy privacy management strategies for themselves and others (Baruh and Popescu
39
40 2017), and to challenge unethical actions that seek to undermine or subvert the truth-value of
41
42 data-driven systems and practices (De Laat 2018). The 'quantified self' movement emphasises
43
44 how we collect and share big data about ourselves, and 'quantified employees' may be able to
45
46 actively choose to anonymously share data they collect to hold management accountable
47
48 through emerging websites and apps like Glassdoor (Bersin 2014).
49
50
51
52
53

54 Top-down and bottom-up forms of analytics education should include a discussion around
55
56 and clear policy on the ownership of data, covering guidance on responsibilities for ownership,
57
58 handling of data, and consent (Jeske and Shultz 2016). Stakeholder groups, including
59
60

1
2
3 prospective employees, can learn about and jointly enforce the values and rules of data
4 management ethics in conjunction with legal guidelines and data security imperatives (Jagger
5 2016). Publications by Angrave et al. (2016), boyd and Crawford (2012), Davenport et al.
6 (2010), Guzzo et al. (2015), and Kitchin (2014) all represent highly recommended starting
7 points for readers interested in learning more about practical applications and social and ethical
8 issues surrounding big data in organisations and societies.

17
18

19 ***Managing data participation and privacy expectations***

20 Dekas and McCune (2015) summarised several crucial questions for practitioners interested in
21 using employee data in their data efforts. One of the questions asks if employers can expect
22 employees to accept data collection as a form of research, and thus “assume [that] the research
23 and application of findings are an expected or reasonable part of operating a
24 business/organization” (Dekas and McCune 2015, p. 564). Even if confidentiality is assured
25 and the inclusion of employee records presents no privacy risk to the employee, the basic
26 question remains as to whether an employer can indeed justify the use of complex and detailed
27 employee data as the best source of information to run a business effectively (Dekas and
28 McCune 2015).
29
30
31
32
33
34
35
36
37
38
39
40
41

42 It may be judicious to start discussing employee expectations about what data is collected
43 and shared. This also includes the degree to which employee data are employed, and for what
44 purposes. Furthermore, clarity and expectations should be set in context around how likely it
45 is that specific data will be used to inform decisions regarding the employment relationship
46 (including retention, promotion, or pay rises). The use of data, their handling and role in the
47 implementation of HR strategies and practices need to be clear from the start to avoid another
48 ‘black box’ in HR.

Privacy and protection expectations will be influenced by how employers continue to make use of the data collected about individual employees (e.g. extending onsite data collection into offsite periods). Clearly Amazon's use of wireless wristbands to capture big data about its warehouse workers violated expectations about protecting workers' rights, but this prompted Amazon to respond by managing expectations that it would also be used to support employee well-being, not just productivity (Green 2018). Big data can itself also be part of the solution to managing employee expectations about other issues – for example, where the chief HR officer of IBM used social media data to detect employee dissent about a controversial travel ban and was able to communicate a reversal of the decision within 24 hours (Green 2018). Being clearer about the stages, durations, lifetimes, and different criteria of big data processing in employment are ways to break down the issue and unpack the nuances of different types of privacy expectation through more democratic and inclusive discussion (Chen and Yan 2016).

Purposeful design for data collection and use

Designing both data collection and data usage approaches with ethical purpose and adequate privacy are, we argue, important considerations for employers seeking to gain the most useful insights from big data; namely, to improve working conditions and address employee or organisational performance issues. The 2018 General Data Protection Regulation (GDPR) framework plays a pivotal role in many European workplaces, but we provide some key additional points here.

Any big data project in a workplace will involve decisions over the types of data considered, their collation, communication, and subsequent storage and usage, with the potential for ethical issues to arise at each step (Bazerman and Tenbrunsel, 2011). In addition, especially where algorithms, automation, and machine learning are involved, the data that organisations acquire from different devices and streams will require only minimal human agency or intervention.

1
2
3 This has additional ethical implications for the personal freedom and integrity of those
4 stakeholders yielding the data (Fung 2015; Zwitter 2014). It may not even be necessary to force
5
6 continuous monitoring of employees. Big data analytics can enable predictions to be made
7
8 about employees who do not give consent (Custers, 2016), by using equivalent information
9
10 from those who gave consent and who share at least some similar characteristics, according to
11
12 a variety of data sources (Kosinski et al. 2013).
13
14
15

16
17 Nevertheless, some restrictions on data collection are within the control of the employer and
18
19 can be used to ensure more positive reactions to big data initiatives. Privacy protocols can act
20
21 to anonymise employees by stripping identifying information from devices. This needs to be
22
23 balanced against the fact that if the data is stripped of too many identifying marks the
24
25 functionality of the devices is affected, and utility for big data analytics will be greatly reduced.
26
27 The combination of datasets may still enable analysts to de-anonymise them, despite these
28
29 precautions (Nunan and Di Domenico 2017), as in the case of triangulation. Overall, this means
30
31 that designing resilient systems with transparent and reasonable purposes and for privacy
32
33 should be a vital to managing employment relations, employee expectations, commitment to
34
35 the employer and the psychological contract. By implication, this suggests greater recognition
36
37 of trade-offs among design criteria, such that the extensiveness of data collection via different
38
39 devices and means may exist in tension with the attempts to design for privacy.
40
41
42
43

44
45 Beyond design for privacy, there is also the intention behind the combination of datasets
46
47 that needs to be fit for purpose. In sum, device functionality, the purpose of data collection,
48
49 and personal rights need to be carefully balanced (Li et al. 2016). Accordingly, authors like
50
51 Guzzo et al. (2015) have produced further research guidelines for working with big data. These
52
53 focus on consent, privacy and personal information (protection strategies to maintain data
54
55 privacy), but also the need to consider issues regarding the actual integrity of data and data
56
57
58
59
60

1
2
3 analysis (e.g. reporting on sampling issues, measurement and data quality, and minimization
4
5 of potential harm).
6

7
8 Big data collection cannot and perhaps should not be unduly restricted, but where there is
9
10 ample data access and collection occurring in employment settings, responsible usage should
11
12 be encouraged and irresponsible misuse discouraged, beyond its collection. The work of Tom
13
14 Davenport (e.g. Davenport et al. 2010; Davenport and Kudyba 2016) is particularly helpful on
15
16 the various uses, abuses, and mistakes involved in using analytics and data-driven approaches
17
18 to frame important insights and decisions. Responsible usage tends to revolve around
19
20 normative considerations, such as fairness, inclusion, transparency, and the need for robust and
21
22 flexible interpretation. Using data analytics for carefully designed and responsibly limited
23
24 purposes flows from the data collection phase, but also takes people analytics away from being
25
26 more of a fad and more toward being a genuinely innovative and valuable technique
27
28 (Rasmussen and Ulrich 2015).
29
30
31
32

33
34 One possibility is that big data analytics can generate a provocative shock or serve as a
35
36 catalyst for more innovative modes of knowledge production in and about workplaces,
37
38 counteracting the flaws of more traditional uses of data, such as deductive hypothesis-testing
39
40 and excessive theory-building. Potentially, less *deductive* attention would be paid to
41
42 cumbersome issues of theories and methodologies, and more *inductive* attention to open
43
44 exploration of puzzling phenomena and drawing equally open, unbiased conclusions (Chiaburu
45
46 2016; McAbee et al. 2017).
47
48
49
50

51 **Embracing ethical big data leadership – A final comment**

52
53 We wish to conclude with one final recommendation that we feel should become a core
54
55 component of leadership in business, particularly for those using big data analytics. This is the
56
57 assertion that ethical leadership in terms of data collection and management will be essential
58
59
60

1
2
3 to informing and guiding employees and managers in the here and now, as well as in the future.
4
5 To date, Silicon Valley ethics and leadership failures are well-documented, and are arguably
6
7 not setting the bar high enough for other organisations and employers increasingly engaging in
8
9 big data (Gobble 2018).
10
11

12 Our data-related decisions, considering current and expanding storage capacities, could have
13
14 major implications for the lifelong working experience of employees, where there are new
15
16 requirements to support data transportability rights - according to the 2018 General Data
17
18 Protection Regulations, for example. Having an ethical role model has been shown to positively
19
20 contribute to higher levels of subordinate-rated ethical leadership in organisational behaviour
21
22 (Brown and Trevino 2014). Ethical leadership itself has been defined by Brown and Trevino
23
24 (2006), both in terms of leaders being morally guided in their general interaction with others
25
26 (a moral person), as well as behaving ethically in the context of working alongside others (a
27
28 moral manager).
29
30
31
32

33 Ethical leadership thus requires not only fair and principled decision-making, but also the
34
35 role modelling of ethical standards, the communication of ethical standards and holding those
36
37 infringing on ethical standards accountable for their actions. Many of these behaviours will
38
39 play an important role when employers use data analytics that include large datasets based on
40
41 employees' interactions, social network engagements, and behavioural traces. Ethical
42
43 leadership has also been positively linked to the consideration of employees, trust in leaders,
44
45 honesty, and interactional justice (Brown, Trevino, and Harrison 2005). Embracing ethical
46
47 leadership skills, therefore, has become highly significant and relevant as data collection at
48
49 work becomes more prevalent, and the need for data to work for the benefit of employees as
50
51 well as employers becomes more urgent.
52
53
