70 declared funding support from YCR and RfPB; no financial relationships with any  
71 organisations that might have an interest in the submitted work in the previous three years,  
72 no other relationships or activities that could appear to have influenced the submitted work.

73

74 **Abstract**

75 **Objectives**

76 Stereotactic Ablative Radiotherapy (SABR) is a well-established treatment for medically  
77 inoperable peripheral stage I non-small cell lung cancer (NSCLC). Previous non-randomised  
78 evidence supports SABR as an alternative to surgery, but high quality randomised controlled  
79 trial (RCT) evidence is lacking. The SABRTooth study aimed to establish whether a UK  
80 phase III RCT was feasible.

81 **Design and Methods**

82 SABRTooth was a UK multi-centre, randomised controlled feasibility study targeting patients  
83 with peripheral stage I NSCLC considered to be at higher-risk of surgical complications.  
84 Fifty-four patients were planned to be randomised 1:1 to SABR or surgery. The primary  
85 outcome was monthly average recruitment rates.

86 **Results**

87 Between July 2015 and January 2017, 318 patients were considered for the study and  
88 205(64.5%) were deemed ineligible. Of 106 assessed as eligible (33.3%), 24 patients  
89 (22.6%) were randomised to SABR (n=14) or surgery (n=10). A key theme for non-  
90 participation was treatment preference with 43 (41%) preferring non-surgical treatment and  
91 19(18%) preferring surgery. The average monthly recruitment rate was 1.7 patients against  
92 a target of 3. Fifteen patients underwent their allocated treatment, 12 SABR, 3 surgery.

93 **Conclusions**

94 We conclude that a phase III RCT randomising higher-risk patients between SABR and  
95 surgery is not feasible in the National Health Service (NHS). Patients have pre-existing  
96 treatment preferences, which was a barrier to recruitment. A significant proportion of patients  
97 randomised to the surgical group declined and chose SABR. SABR remains an alternative to  
98 surgery and novel study approaches are needed to define which patients benefit from a non-  
99 surgical approach.

100

101

102

103 **Introduction**

104 Stage I non-small cell lung cancer (NSCLC) is curable, with surgery considered the standard  
105 of care for medically fit patients. Reported 5-year overall survival (OS) rates range from 53-  
106 89% for stage IA1-3 disease and 49-71% for stage IB disease (1). However, a significant  
107 proportion of patients with Stage I NSCLC are not suitable for surgery because of their age  
108 and/or poor fitness, often related to a patient's significant medical co-morbidities. This is  
109 confirmed in the UK with data from the most recently published National Lung Cancer Audit  
110 (NLCA) where only 60.6% of stage I-II patients with a performance status of 0-2 underwent  
111 surgery (2). This confirms that a significant proportion of patients are deemed to be at higher  
112 risk of surgical complications including death.

113 An alternative approach to treating these 'higher risk' is stereotactic ablative radiotherapy  
114 (SABR). For medically inoperable peripherally located stage I NSCLC, SABR has been  
115 shown to have improved overall survival rates and better local control (3) and better quality  
116 of life (4) when compared with conventional fractionated radical radiotherapy. Propensity  
117 matched retrospective series of SABR in operable patients suggest that SABR may be an  
118 alternative to surgery whilst others have favored surgery (5-8). A systematic review of  
119 studies published between 2006 and 2013 showed an equivalent 2-year OS between SABR  
120 and surgery (9) and similarly, a meta-analysis of articles published between 2000 and 2012  
121 indicated no significant difference in OS between the two treatment strategies (10). Finally, a  
122 single-centre competing risk analysis has shown no difference in cancer-specific survival  
123 between SABR and surgery in unmatched patients (11)

124 However, all these analyses are limited due to the quality of the retrospective data and, even  
125 with propensity matching; case selection and other significant factors (e.g. specific co-  
126 morbidity, smoking history, and socio-economic factors) cannot be accounted for fully.  
127 Randomised trials for medically operable patients have been attempted in the past and  
128 closed prematurely due to failure to recruit (ROSEL (NCT00687986), STARS  
129 (NCT00840749), and ACOSOG-RTOG (NCT01336894) (12-14). A pooled analysis of the  
130 STARS and ROSEL trials suggested that SABR was better tolerated and may lead to better  
131 OS than surgery for operable stage I NSCLC. This pooled analysis provoked significant  
132 debate in the lung cancer community and the consensus was that a larger RCT was required  
133 to validate these results (13). Researchers involved in the ACOSOG – RTOG trial  
134 recommended that such a study would require commitment by investigators when  
135 discussing the trial with patients and close collaboration between surgeons and radiation  
136 oncologists (14). Ultimately, clinician and patient acceptability of a challenging randomisation  
137 between SABR and surgery is key to the successful conduct of such trial.

138 The main challenge when trying to compare two very different treatment modalities with  
139 differing toxicity and treatment-related mortality profiles is to achieve equipoise amongst  
140 clinicians and patients. The aim of the SABRTooth study was to determine the feasibility and  
141 acceptability of conducting a large definitive phase III RCT comparing surgery with SABR in  
142 patients with Stage I NSCLC deemed to be at a higher risk of surgical complications.

143

## 144 **Material and Methods**

### 145 **Study design and participants**

146 The SABRTooth study was a UK-based, multi-centre, open-label, parallel-group randomised  
147 controlled feasibility study in patients with peripheral stage I NSCLC considered to be at  
148 higher risk of complications from surgical resection.

149 In total, 54 patients were planned to be recruited to provide evidence that when recruitment  
150 rates were scaled up, a large-definitive phase III RCT would be possible. Recruitment was  
151 from four established thoracic surgical centres and one selected larger referral unit.

152 Ethical approval was granted by Yorkshire and The Humber – Leeds West Research Ethics  
153 Committee (ref: 14/YH/1162). All patients provided written informed consent.

154 Full details of the study protocol have been published previously (15). Patients were  
155 identified by lung cancer teams through the multi-disciplinary team (MDT) meetings, after  
156 assessment of eligibility. The core eligibility criteria did not change during the study (Table  
157 1). Guidance for defining patients at a higher-risk from surgical complications from a  
158 lobectomy was based on national and international standard criteria (e.g. lung function,  
159 performance status, fitness assessment), Thoracoscore and the “Nottingham” nomogram  
160 (Table 2) (16). Pre-treatment investigations were as reported previously (15). All data/scores  
161 were recorded prospectively but ultimately, the final decision on patient eligibility rested with  
162 the local MDT.

### 163 **Randomisation and masking**

164 Patients were randomised (1:1) to surgery or SABR using a 24-hour telephone or web-based  
165 system centrally governed by the Clinical Trials Research Unit, University of Leeds (15).

### 166 **Procedures**

167 Treatment was aimed to start within 31 days of randomisation, in line with NHS guidelines.

168 The aim of surgery was a R0 resection; both thoracotomy and Video Assisted Thoracoscopic  
169 Surgery (VATS) were acceptable. The recommended procedure was an anatomical resection,  
170 ideally by lobectomy or an anatomical segmentectomy if not suitable for lobectomy. Sub-lobar

171 or wedge resection was acceptable if an anatomical resection was not deemed possible by the  
172 treating surgeon. Sampling of at least three lobe-specific N2 nodal stations was  
173 recommended, though for wedge resections lymph node sampling was not mandated, as, due  
174 to patient factors, the duration of the anaesthetic may need to be minimised. Post-operative  
175 care was as per local unit protocols. Participants who were assessed as being unfit for surgery  
176 pre-operatively were treated according to local guidelines.

177 SABR treatment was based on the accepted guidelines of the UK SABR consortium (17) for  
178 peripherally located stage I NSCLC, with three dose schedules based on the location of the  
179 tumour (supplementary material). Where participants were unable to receive their allocated  
180 treatment, e.g. if a SABR plan didn't meet planning objectives, radical radiotherapy or  
181 surgery would be considered according to local guidelines. Radiotherapy quality assurance  
182 was provided by the NCRI Radiotherapy Trials Quality Assurance Team (RTTQA). Details of  
183 the trial radiotherapy quality assurance are contained in the supplementary material:  
184 SABRTooth Radiotherapy Guidelines.

185 Treatment related complications were treated as per local guidelines.

#### 186 **Data collection**

187 All patients considered for the study were 'tracked' up until the point of randomisation to  
188 establish reasons for drop-out. Follow-up frequency and data collection was as previously  
189 reported (15) and in line with current NHS practice.

190 Complications, defined as any untoward medical event that has a causal relationship to the  
191 study or administration of any procedures, were collected from the end of surgery or final  
192 SABR administration until the end of the follow-up period. Serious complications (SCs) and  
193 unexpected serious complications (USCs) required reporting within 30 days of surgery or final  
194 SABR administration.

195 A qualitative sub-study explored in up to 15 patients, their acceptability of the study. Eligible  
196 patients who declined study participation, or participants who were randomised but did not  
197 take up their treatment allocation were invited to take part in a feedback interview to identify  
198 reasons for their choices.

199 Intended recruitment pathways were captured via site-specific visits prior to the start of  
200 recruitment. A follow-up questionnaire captured changes to intended recruitment pathways,  
201 tools/criteria used to identify eligible patients and factors perceived to be a driver or challenge  
202 to recruitment.

#### 203 **Outcomes**

204 The primary objective of the study was to quantitatively assess recruitment rates i.e. patients  
205 providing consent for randomisation into the study, regardless of uptake of their randomised  
206 treatment procedure. An average rate of three patients per month across the five centres  
207 was needed over a formal monitoring period to demonstrate that a phase III trial would be

208 feasible in the UK. The formal monitoring of recruitment period began 6 months after the  
209 start of recruitment (allowing for a run-in period for site set-up) for 13 months. Table 3 details  
210 the secondary and exploratory objectives.

### 211 **Recruitment strategies**

212 Significant efforts were made during study development to optimise recruitment. During the  
213 study, aspects of the recruitment strategy were modified based on feedback received from  
214 sites and patients. Aspects of these approaches are detailed in Table 4.

### 215 **Statistical analysis**

216 The final analysis took place after the final participant had been followed up for 6 months.  
217 Analyses involved descriptive and summary statistics and no formal hypothesis testing was  
218 conducted. The primary endpoint analysis was based on the population of patients recruited  
219 during the formal monitoring period. The treatment and safety data are presented for the  
220 safety population, i.e. participants who received at least one dose of radiotherapy or who  
221 underwent surgery. The screening data is presented for the screening population, i.e.  
222 patients who were screened for entry into the study All further analyses were carried out  
223 using the intention-to-treat (ITT) population.

224 All analyses were performed in SAS version 9.4.

225 A Trial Steering Committee (TSC) met to review the safety and ethics of the study prior to  
226 opening to and during recruitment.

227

### 228 **Results**

229 Between 1 July 2015 and 31 January 2017, 318 patients were considered for the study. 106  
230 (33.3%) were initially assessed as eligible and 84 (79.2%) were approached to take part. In  
231 total, 24 patients were randomised (28.6%), 14 to SABR and ten to surgery from five UK  
232 centres (Figure 1). The last date of patient follow-up was in July 2017.

233 Figure 2 presents the flow of patients through the screening process and reason for patients  
234 not assessed as eligible, not approached or declining randomisation where known. The trial  
235 population was representative of the general lung population with stage I NSCLC. Of the 84  
236 patients initially assessed as eligible and approached for the study, 52 (61.9%) declined  
237 randomisation with 42.3% (n=22) preferring SABR and 28.8% (n=15) for surgery; eight  
238 patients did not want surgery, six did not wish to enter a trial and one patient did not specify  
239 a reason.

240 Table 5 presents the baseline demographic and disease related characteristics of the  
241 randomised study population. The median age was 75 years (54-88) and the majority were  
242 female (n=14, 58.3%). All but one participant presented with one or more pre-existing  
243 condition. Surgical participants had a larger median tumour size (2.7 vs 1.9cm) and greater  
244 proportion of stage T2a tumours (70.0% vs 21.4%) compared to SABR.

245 Twenty-four patients were randomised over the whole recruitment period (14 SABR, 10  
246 Surgery). With a median recruitment rate of 4 patients across the 5 recruiting centres  
247 (range: 1, 9). The formal assessment of the primary endpoint began 6 months after the start  
248 of recruitment and over the 13-month formal monitoring of recruitment period, 22 patients  
249 were randomised (12 SABR, 10 Surgery). There was an average recruitment rate of 1.7  
250 patients per month falling short of the required three patients per month to meet the primary  
251 endpoint and demonstrate feasibility of recruitment. All five recruiting sites recruited to the  
252 study.

253 Of the 24 participants randomised, 62.5% (n=15) underwent their allocated treatment  
254 procedure; 30.0% (n=3) of participants randomised to surgery compared to 85.7% (n=12)  
255 randomised to SABR (Figure 1). Of the seven participants not undergoing surgery, all were  
256 tumour stage T2a. Five did not wish to have surgery and two were deemed to be ineligible  
257 post-randomisation (Figure 1). All seven participants went on to receive radiotherapy (six  
258 SABR, one conventionally fractionated radiotherapy). In the SABR group, one participant  
259 was deemed ineligible post-randomisation and received radical radiotherapy; the final  
260 participant was lost to follow-up.

261 Median time from randomisation to start of treatment for the 3 surgery and 12 SABR  
262 participants was 38 days (range: 20 to 61) and 29 days (range: 19 to 48) respectively. All  
263 participants who underwent protocol treatment received it as planned. The surgical  
264 procedure undertaken was either VATs (n=2) or open (n=1). SABR dose fractionation was  
265 as per the UK SABR Consortium guidelines with 3 participants receiving 54 Gy in 3 fractions,  
266 8 receiving 55Gy in 5 fractions, and 1 receiving 60Gy in 5 fractions. Median time between  
267 surgical operation date and date of discharge was 13 days (range: 4 to 15). Median time on  
268 study measured from randomisation to date of last follow-up, withdrawal or death was 9.2  
269 months (range: 0.2 to 20.3), 11.8 months (range: 4.1 to 20.3) for SABR and 7.6 months  
270 (range: 0.2 to 12.7) for surgery.

271 Table 6 presents the compliance rates with the EQ-5D-5L and EQ-VAS questionnaires.  
272 Compliance rates for the QLQ-C30, QLQ-LC13 and Use of Resources questionnaires were  
273 similar and for returned questionnaires, the completion rates were high. The mean and  
274 standard deviation of the EQ-5D utility scores (where scores could be derived) for surgery

275 and SABR respectively were 0.8(0.22) (n=10) and 0.8(0.09) (n=14) at baseline; 0.9(0.14)  
276 (n=5) and 0.8(0.11) (n=13) pre-treatment; 0.7(0.35) (n=7) and 0.8(0.11) (n=13) at 6 weeks;  
277 0.7(0.34) (n=6) and 0.7(0.20) (n=12) at 3 months; 0.7(0.45) (n=4) and 0.7(0.17) (n=10) at 6  
278 months. Beyond this, data are limited in the surgical group. Summaries of the QLQ-C30,  
279 QLQ-LC13 and Use of Resources questionnaires are available on request.

280 In the surgical group, 23.8% (5/21) of all the reported complications were CTCAE grade 3  
281 compared to 8.7% (6/69) of events in the SABR group. All complications were attributed to  
282 protocol treatment and were expected.

283 At the time of final analysis there were three participant deaths. One occurred four days  
284 post-surgery due to a post-operative bronchopneumonia in a patient with ischaemic heart  
285 disease. Two participants in the SABR group died 326 and 405-days post-treatment due to  
286 progressive lung cancer and unrelated septicaemia.

## 287 Qualitative Research

288 Twelve patients took part in the qualitative interviews, nine who had declined participation  
289 and three who declined to take up their randomised allocation to surgery. These patients had  
290 a clear preference for surgery or SABR. Further details are provided in the supplementary  
291 material, but key themes included: 1) the complexity of decision making when choosing  
292 between different treatments alongside the decision to take part in a trial; 2) patients making  
293 sense of their decision by talking to health care professionals, family and friends, or using  
294 their own prior experience or knowledge of the treatment.

295 Recruitment pathways were similar between sites as presented in the supplementary  
296 material. However, strategies for introducing and discussing the study with patients were  
297 adapted in each centre. Mentioning the study earlier in the patient pathway was found to be  
298 helpful and did not overburden patients with information. Table 7 presents a summary of the  
299 perceived challenges to recruitment, and factors believed to encourage recruitment from a  
300 site perspective.

301 The assessment criteria and tools used to identify suitable study patients varied between  
302 sites. MDT opinion and ECOG performance status were always used.

303

## 304 Discussion

305 The SABRTooth feasibility study failed to achieve the predefined recruitment target of an  
306 average of three patients per month during the 13-month formal monitoring period;  
307 demonstrating that a larger phase III RCT of SABR versus surgery is not possible in the UK.

308 Despite the lower than anticipated recruitment, a great deal of insight was obtained about  
309 running a trial in this context in the UK.

310 Multiple secondary endpoints were studied to evaluate the most optimal study design and  
311 explore reasons for participation/non-participation. Adaptation and learning were built into  
312 the trial, employing strategies that had been successful in other randomised trials between  
313 surgery and non-surgical treatments (18). The recruitment strategy was modified  
314 throughout the study based on feedback from sites and through greater understanding the  
315 complexity of the conversations between patients and clinicians when discussing this trial.  
316 Alternative approaches to randomisation were also considered including the pre-  
317 randomisation model employed in the STABLE-MATES trial (NCT02468024). It was felt that  
318 there was insufficient evidence, and concerns around the methodological robustness of this  
319 design to support this change during the recruitment period of SABRTooth (19).

320 The reasons for the SABRTooth study failing to recruit are complex and reflect both pre-  
321 existing patient and clinician preferences as detailed in Table 7.

322 Consenting and randomising patients prior to meeting the treating surgeon or oncologist by a  
323 research lung research nurse and/or respiratory physician was intended to remove treating  
324 clinician bias but may also have contributed to the high surgical dropout. Education and  
325 training were provided before and during the SABRTooth study to the research nurses and  
326 respiratory physicians to try and optimise the explanation of the trial and facilitate consent.  
327 Given the relatively small numbers of researchers and patients it was not possible to assess  
328 if clinician bias consciously or subconsciously influenced the patients and hampered  
329 patient's acceptance of randomisation. However, it is important to note that approximately  
330 70% of the patients who were considered eligible but declined the study had a preference for  
331 non-surgical treatments and were predominantly older with significant comorbidities.

332 Targeting "higher-risk" patients reduced the number of potential eligible patients but reflected  
333 patients for where there is most clinician equipoise between surgery or SABR. Approached  
334 patients found the study information to be clear and well-presented which often prompted  
335 more in-depth conversation with clinicians regarding their treatment options. Therefore, all  
336 approached patients would have been aware they were higher risk for surgery and been  
337 more aware of all the treatment options, particularly the option of a non-surgical approach.  
338 This may have influenced the patient's equipoise as patients had a clear preference for one  
339 of the treatment options when asked. Patients were clear that this was personal decision  
340 which they wanted to make for themselves, often after talking to health professionals, family  
341 or friends.

342 In an era of increasing availability of information of treatment options, through formal  
343 literature, on-line information and patient forums, patients are, and will continue to be better  
344 informed of their treatment options. The SABRTooth study has shown that the majority of  
345 eligible patients, when given further information on both options, have a treatment  
346 preference for a non-surgical approach, both in the screened population and for those  
347 patients randomised to surgery.

348 We need to involve patients in the treatment decision-making process and a shared decision  
349 making (SDM) approach is of growing interest in oncology studies. This is particularly  
350 relevant when the treatment options are preference sensitive i.e. when there are multiple  
351 suitable treatment options. It is however recognised that incorporating SDM into daily clinical  
352 practice brings its own challenges (20) and requires skilled clinicians, a combination of  
353 interventions that support the patient, clinician and organisation and “buy-in” from the clinical  
354 team and organisation (21).

355 SABRTooth has shown that it is not feasible to randomise higher-risk stage I non-small cell  
356 lung cancer patients to surgery or SABR in the NHS. However, there are ongoing RCTs in  
357 similar populations (at the time of publication) which include the VALOR (NCT02984761 and  
358 STABLE-MATES (NCT02468024) studies which are open to recruitment in North America  
359 and may answer this important research question.

360 Further work is required to address the issues raised in the SABRTooth study. Whilst a  
361 randomised trial might be feasible where there are sufficient resources to address the  
362 equipoise of all involved, the extent to which this could be applied in routine clinical practice  
363 would be limited. Thus, randomising between SABR and surgery is challenging within the  
364 NHS, particularly when focusing on a well-informed selected older population with  
365 comorbidities. Despite RCTs being considered a gold standard framework for evaluating  
366 clinical trials, they are not always suitable to answer every question. Alternative strategies are  
367 needed to provide the evidence to assist policy makers, practitioners and patients to decide  
368 the most appropriate treatment. Future studies for high-risk patients with stage I/II NSCLC  
369 may benefit from non-randomised designs that take account of the decision making and  
370 preferences of the patients and clinicians as part of shared decision making.

371

## 372 **Contributors**

373 KNF, LMcP, WG, DRB, DSM, CFF, JH, JB, FC, PA, AS and MS conceived and designed the  
374 study. RN, CO and SB coordinated the study and collected and validated the study data.

375 ME, RB, CFF, BN, JF, CP, MEJC, MK and JB recruited patients to the study. LMcP, JW, JB,

376 JH and PH analysed the data. All authors approved the final version of the publication. KNF  
377 and LMcP are responsible for the overall content of the article as guarantors.

378 The corresponding author attests that all listed authors meet authorship criteria and that no  
379 others meeting the criteria have been omitted.

380

### 381 **Acknowledgements**

382 This paper/abstract/presentation presents independent research funded by the National  
383 Institute for Health Research (NIHR) under its Research for Patient Benefit (RfPB)  
384 Programme (Grant Reference Number PB-PG-0613-31114). The views expressed are those  
385 of the author(s) and not necessarily those of the NHS, the NIHR or the Department of Health  
386 and Social Care. The study also receives support be clearer what for from Yorkshire Cancer  
387 Research (Award reference number: L375PA).

388 The authors would like to thank all participants and hospital staff who contributed to this  
389 study. The authors would also like to thank the TSC for their study oversight, and the  
390 patients and public representatives on both the TSC and Trial Management Groups (TMG).

391

### 392 **Data sharing**

393 The study data can be made available via a controlled access approach  
394 (<https://trialsjournal.biomedcentral.com/articles/10.1186/s13063-015-0604-6>) upon  
395 reasonable request. Requests for data access should be directed to Dr Kevin Franks  
396 [kevin.franks@nhs.net] in the first instance.

397

### 398 **Transparency declaration**

399 The joint first authors (KNF and LMcP) affirm that the manuscript is an honest, accurate, and  
400 transparent account of the study being reported; and that no important aspects of the study  
401 have been omitted; and that any discrepancies from the study as planned have been  
402 explained.
