15

16 Abstract

17 The main objective of this systematic review was to provide a comprehensive overview of
18 the psychometric properties of all available Orthorexia Nervosa (ON) assessment tools, in
19 order to evaluate their scope of application for research and practice. Ten databases were
20 searched for studies quantitatively assessing ON. The psychometric properties were
21 evaluated according to specified quality criteria, focusing on the reliability, structural validity
22 and construct validity of the scales. A meta-analytic approach was used to summarize
23 eligible Cronbach's alpha coefficients between studies. Sixty-eight unique studies fulfilled the
24 inclusion criteria for this systematic review. Ten discrete ON scales were identified. Half of
25 the included studies exclusively utilized a version of the ORTO-15. The evaluation of all
26 available ON measures raise issues regarding ON's dimensionality and conceptualization.
27 Most of the identified scales require further validation. Based on the reported psychometric
28 properties it is advised to re-evaluate existing tools and to focus on establishing consensus
29 regarding the conceptualization of ON to establish a measure with sound psychometric
30 properties.

32 Generalization

33

34 **1 Introduction**

35 **1.1 Rationale**

36 Orthorexia Nervosa (ON) has been defined as a pathological obsession, fixation or
37 preoccupation with healthy food (e.g. Andreas et al., 2018; Barrada & Roncero,
38 2018; Barthels, Meyer & Pietrowsky, 2015b; Bauer et al., 2019; Brytek-Matera et al.,
39 2014; Chard et al., 2018; Glen & Gleaves, 2018; Haddad et al., 2019; He et al.,
40 2019; Rogoza, 2019), a new eating disorder (Donini et al., 2005) or “[...] an
41 otherwise healthy behavior [...] taken to extremes [...]” (Gleaves et al., 2013, p. 1).
42 However, ON has so far not been recognized by the Diagnostic and Statistical
43 Manual of Mental Disorders (5th ed.; DSM-5; American Psychiatric Association,
44 2013) or the international statistical classification of diseases and related health
45 problems (ICD-11; World Health Organization, 2018).

46 Despite the lack of universally accepted diagnostic criteria, ON has been studied
47 increasingly in the last two decades, which resulted in the publication of four
48 classification approaches defining possible diagnostic criteria (Setnick, 2013; Moroze
49 et al., 2015; Barthels, Meyer & Pietrowsky, 2015b; Dunn & Bratman, 2016). All these
50 approaches refer to an obsessional or pathological preoccupation with healthy
51 nutrition, emotional consequences for transgressing self-imposed dietary rules and
52 psychosocial impairments due to ON (Cena et al., 2018). However, in direct
53 comparison the four approaches differ regarding individual criteria, including
54 conceptual contradictions. For example, while Setnick’s (2013) approach includes
55 ‘phobic avoidances’ and an interrelation between a restrictive diet and an ostensible

56 medical condition, Moroze et al. (2015) suggest that ON should only be diagnosed if
57 a specialized diet is not related to diagnosed food allergies or medical conditions
58 calling for this diet. Furthermore, Barthels, Meyer and Pietrowsky's (2015b) criteria
59 specify that an *intended* weight loss and underweight may be present, while Dunn
60 and Bratman (2016) include the absence of a desire to lose weight as essential for
61 the diagnosis of ON.

62 Discrepancies in the conceptualization of ON impact the validity of ON measures.
63 Existing ON scales, or the lack of a standardized measure, have been criticized by
64 multiple reviews (e.g. Valente, Syurina & Donini, 2019; Costa, Hardan-Khalil &
65 Gibbs, 2017; Missbach, Dunn & König, 2017; Missbach et al., 2015; Koven & Abry,
66 2015). However, no review so far has systematically evaluated the psychometric
67 properties of all the available measures. In order for ON research to move forward, it
68 needs to be clear how existing measures perform in comparison to one another.

69 **1.2 Objectives**

70 This systematic review has two main aims. First, to identify all quantitative measures
71 assessing ON, and second to evaluate these measures' psychometric properties.

72 **2 Methods**

73 **2.1 Protocol and Registration**

74 The review protocol was registered on International prospective register of
75 systematic reviews (PROSPERO, registration number CRD42019131090) in April
76 2019, in order to ensure its transparency and quality standards (Booth, 2012; Sideri,
77 Papageorgiou, & Eliades, 2018). The protocol was updated on 17th December to
78 include a reliability generalization (RG) analysis. The RG analysis was added to the

79 protocol as it provides additional information for the analysis of psychometric
80 properties.

81 **2.2 Eligibility Criteria**

82 For this systematic review, all studies assessing ON with a quantitative measure
83 were included, as long as they reported at least one of the psychometric properties
84 specified as part of this review (Internal Consistency, Re-test Reliability, Structural
85 Validity and Construct Validity as determined in relation to established measures).
86 ON had to be assessed with one of the following methods: the application of a
87 questionnaire, inventory, single-question, scale or subscale. Published literature,
88 grey literature (OpenGrey) and master's as well as doctoral theses (ProQuest
89 Dissertations & Theses Global) were eligible for screening. No limit was set
90 regarding the publication date and all articles written in English, German, French,
91 Dutch and Spanish were included. These languages were chosen based on the
92 language proficiency of the first author (MCO). Any other languages were excluded
93 ($n = 12$) as no translation software was used in order to avoid misinterpretations.
94 Excluded were reviews ($n = 12$) and studies reporting the same results in more than
95 one publication ($n = 8$), to avoid multiple publication bias.

96 **2.3 Information Sources**

97 EMBASE, PubMed/MEDLINE, Scopus, PsycInfo, Web of Science, ProQuest
98 Dissertations & Theses Global, ASSIA, CINAHL, OpenGrey and ETHOS were
99 searched for titles and abstracts, once in April 2019 and once in August 2019, in
100 order to update the literature search.

101 **2.4 Search Strategy**

102 The search terms were based on a pilot screening of titles and abstracts, which
103 identified relevant questionnaires and spellings. These were specified as “Orthorexi**”
104 (accounting for English and German spelling), “Ortore*a” (accounting for Italian,
105 Spanish and Turkish spelling), “Ortorexi” (Swedish), “obsessive healthy eating”,
106 “ORTO-15”, “ORTO-11”, “ORTO-9”, “EHQ”, “Eating Habits Questionnaire” and
107 “Bratman Test”. References and citations were used to identify additional relevant
108 articles. Once duplicates were deleted, missing data was identified and authors were
109 contacted, up to two times, via email if a contact address was provided on the paper
110 or via ResearchGate.

111 **2.5 Study Selection**

112 All studies fulfilling the eligibility criteria were included in the systematic review. For
113 the meta-analytic RG, all studies reporting a Cronbach’s alpha value for the total
114 scale of ON measures were included if at least two values were reported by a
115 minimum of two independent studies (Higgins et al., 2019).

116 **2.6 Data Collection Process**

117 The online tool Covidence was used to coordinate the screening process between
118 the first (MCO) and second (ASAVM) reviewer. Both reviewers screened titles and
119 abstracts on Covidence after extracting them from the search databases. The
120 included texts were assessed in their full-text version by the first author. The second
121 reviewer independently assessed a random sample (20% of the results). Conflicting
122 decisions were discussed in order to reach agreement. A third independent reviewer
123 (MR) screened a different random sample (20% of the final sample) of the full texts
124 included. Psychometric properties were documented in a table to identify the
125 outcomes relevant for this review.

126 **2.7 Outcomes**

127 The studies included were evaluated based on an adapted version of the Quality
128 Criteria for Measurement Properties of Health Status Questionnaires formulated by
129 Terwee et al. (2007) and the COnsensus-based Standards for the selection of health
130 Measurement INstruments (COSMIN) Risk of Bias Checklist (Prinsen et al., 2018;
131 Mokkink et al., 2018; Terwee et al., 2018). Every measure identified was outlined in
132 alphabetical order (Table 1). The evaluation of measurement properties focused on
133 the content validity (conceptual framework, measurement aim, target population and
134 item selection strategy), internal consistency, re-test reliability, structural validity
135 (dimensionality) and construct validity (associations with any other measure) of the
136 individual scales. Internal consistency values were interpreted based on accepted
137 standards (DeVellis, 2003; Nunnally, 1967 in Tavakol & Dennick, 2011).

138 **2.8 Data Synthesis**

139 The results of the systematic evaluation of measurement properties were
140 summarized by measure (the evaluation process is illustrated in the supplementary
141 materials). A summary table was created to compare the findings of all included
142 studies (Table 2). In order to estimate the overall reliability of tests scores for the
143 same measure between studies, an RG was conducted for the Cronbach's alpha
144 values reported. In the present study, a meta-analysis of available reliability
145 coefficients was conducted following Rodriguez and Maeda's (2006) discussion on
146 the "Meta-Analysis of Coefficient Alpha". Based on this study, Cronbach's alpha was
147 transformed using the transformation $T_i = (1 - r_{\alpha i})^{\frac{1}{3}}$ by Hakstian and Whalen
148 (1976) (with r_{α} being the sample coefficient alpha and T_i being the transformed alpha
149 value). This approach was chosen due to the results of Rodriguez and Maeda's
150 comparison of common RG approaches, which showed that T_i exhibited the smallest

151 standard error in comparison to an unweighted mean alpha and a variance-adjusted
 152 alpha coefficient. R_{Studio} was used to calculate the effect sizes using a random-
 153 effects model with the R-code “AHW” for transformed alpha values, as outlined in
 154 <https://cran.r-project.org/web/packages/metafor/metafor.pdf>.

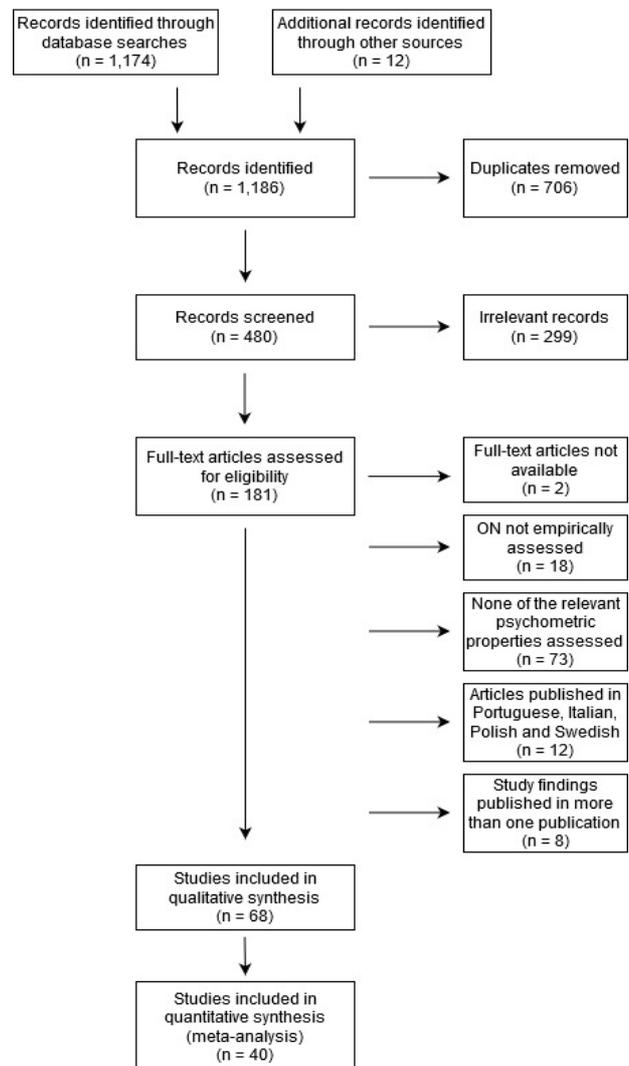

155 3 Results

156 3.1 Study Selection

157 In total, 1,174 studies were identified through the database searches. Eight further
 158 studies were identified by cross-checking the references of included articles and four
 159 unpublished studies were provided

160 by respective authors. Seven-
 161 hundred-and-six duplicates were
 162 removed. Consequently, the first
 163 (MCO) and second (ASAVM)
 164 reviewer screened 480 study titles
 165 and abstracts. This process
 166 identified 299 studies as irrelevant
 167 for this review, as they did not meet
 168 the inclusion criteria (e.g., reports,
 169 letters to the editor, case studies
 170 etc.). As a result, 181 full texts were
 171 assessed for eligibility. The data
 172 extraction was consequently based
 173 on 68 unique studies for the
 174 narrative review and 40 studies for

Figure 1 Flowchart illustrating the study selection process

175 the RG analysis. A flowchart (Figure 1) depicts the details of the search process.

176 Most of the studies included in this review used one version of the ORTO (50%),
177 11.8% used the EHQ, 10.3% a version of the DOS, 4.4% the BOT and 13.2% a
178 combination of measures.

179

180

181

182 **3.2 Psychometric properties**

183 Information on psychometric properties were available for 10 distinct ON measures
184 (Table 1), which varied in their dissemination and utilization. A table illustrating the
185 psychometric evaluation of all ON measures can be found in the supplementary
186 material. Table 2 summarizes the findings per measure.

187 **3.2.1 Body-Image Screening Questionnaire (BISQ, k=2)**

188 Five items of the BISQ assess ON tendencies. The internal consistency for this
189 subscale was identified as insufficient (Cronbach's $\alpha=.59$) and acceptable
190 ($\alpha=.77$) in two different studies, which were conducted in two different countries.

191 **3.2.2 Burda-Orthorexia Risk Assessment (B-ORA, k=1)**

192 The B-ORA was developed as part of a doctoral thesis and has not been evaluated
193 beyond this original study. The internal consistency appeared to be high (Cronbach's
194 $\alpha=.97$) and a single factor was identified after adjusting for error terms. A
195 moderate positive correlation was found with disordered eating attitudes.

196 **3.2.3 Bratman Orthorexia Test (BOT, k=5)**

197 The original questions of the BOT were developed as a personal risk-assessment for
198 people overly concerned with a healthy diet. As measurement theory was not
199 considered for the construction of the BOT, the scale's three different language
200 adaptations utilize differing score interpretations to assess ON. The reported score
201 values for internal consistency range from $\alpha=.67$ up to $\alpha=.79$ for Cronbach's alpha
202 (.60 for the Kuder-Richardson Formula 20). This causes concerns for the scale's
203 reliability, as half of the studies reported a value below .7. The RG analysis revealed
204 an acceptable population alpha of $\alpha_p=.73$, which is based on three alpha values
205 reported for the 10-item version of the BOT. Test-retest reliability has not been
206 assessed so far. The whole scale is moderately to strongly and positively correlated
207 with a measure for disordered eating behavior and eating disorder related eating
208 patterns. One study identified 5 eating disorder specific and 4 ON-specific items for
209 the 9-item version of the scale. The ON-specific items were only weakly correlated
210 with the same measure of disordered eating.

211 **3.2.4 Düsseldorf Orthorexia Scale (DOS, k=10)**

212 The population alpha for the DOS was assessed using 11 Cronbach's alpha values
213 for the 10-item scale, which revealed a coefficient of $\alpha_p=.85$ (Cronbach's alpha
214 ranging from $\alpha=.69$ to $\alpha=.93$). The internal consistency was re-tested within one
215 sample in three-months intervals, which identified consistently acceptable values
216 between $\alpha=.79$ and $\alpha=.84$. The test re-test reliability ranged from $r=.67$ (first 3
217 months interval) to $r=.77$ (4 weeks) and $r=.79$ (second 3 months interval) for the total
218 scale, indicating variable repeatability. The dimensionality of the DOS remained
219 questionable: a single-factor, 3-factorial and 5-factorial structure were found, but
220 poor model fit indices were common in the studies evaluating the DOS. The scale
221 has been shown to be highly positively related to "Drive for Thinness" (Eating

222 Disorder Inventory: EDI, EDI-2), small to moderately to “Body Dissatisfaction” (EDI-
223 2) and variably to “Bulimia” (EDI-2). A high positive correlation was further found with
224 inflexible eating. Hypochondriacal worries and beliefs, as well as “Cognitive
225 Restraint” (Three-Factor-Eating-Questionnaire-Revised: TFEQ-R18) were positively,
226 but only weakly related to the DOS.

227 **3.2.5 Eating Habits Questionnaire (EHQ, k=10)**

228 The total EHQ shows continuously good Cronbach’s alpha values for the total test
229 scores ($\alpha=.86$ up to $\alpha=.94$), with a population alpha $\alpha_p=.85$ for six reported alpha
230 values. The individual subscales slightly differ in their values, which is partly due to
231 the different labels and items authors assign to the subscales (Cronbach’s alpha
232 ranging from $\alpha=.70$ for “Feelings” up to $\alpha=.92$ for “Problems”). Test re-test reliability
233 (after 2-4 weeks) had only been assessed by one study, which found values of $r>.70$
234 for all subscales. Even though a 3-factorial structure was identified by three out of
235 four studies, the item-scale allocation remains inconclusive, based on the reported
236 factor loadings. The total EHQ exhibits small positive correlations with anxiety,
237 depression, perfectionism and narcissistic personality traits. The relationship with
238 measures for disordered eating are less clear, even though consistently positive,
239 ranging from small and moderate to high, with some inconsistencies among studies
240 for the Bulimia-Test Revised (BULIT-R) and the Eating Attitudes Test (EAT-26). The
241 “Problems” scale showed higher correlations with disordered eating (EAT-26, BULIT-
242 R subscales “Body Image/Weight Loss”, “Vomiting/Laxatives”) than the other
243 subscales, a moderate correlation with perfectionism and a weak to moderate
244 correlation with depression. All subscales showed only weak correlations with
245 narcissistic personality traits.

246 **3.2.6 Eating Habits Questionnaire – Revised (EHQ-R, k=2)**

247 The revised EHQ, EHQ-R, is in the early stages of its evaluation. The two studies
248 which assessed its internal consistency reported good Cronbach's alpha values for
249 the total scale and four of the five subscales, with an acceptable Cronbach's alpha
250 value for the subscale "Time Impairment". The suggested 5-factorial structure needs
251 further validation. The same applies for the scale's construct validity. The authors of
252 the tool found large correlations with disordered eating behaviors for the total scale
253 and varying correlation coefficients for the EHQ-R subscales.

254

255

256 **3.2.7 Orthorexia Nervosa Scale (ONS, k=1)**

257 The ten subscales of the ONS showed almost entirely acceptable to excellent
258 internal consistency values (Cronbach's alpha=.70 to α =.92), except for the subscale
259 "Fasting" (α =.69). The measure's author identified the 10-factorial structure with an
260 underlying second-order factor, suggesting that the total ONS scale is measuring
261 one underlying construct. A small positive correlation with food addiction was found
262 for the total scale.

263 **3.2.8 ORTO-15 (k=37)**

264 The most commonly used questionnaire for the assessment of ON was the ORTO-
265 15. So far, the scale has been adapted for seven languages. Nine different ORTO
266 versions were developed by excluding individual items with the aim of improving
267 either the scale's face validity, internal consistency, model fit or factorial
268 interpretability. The reported internal consistency values (Cronbach's alpha) for test

269 scores range from as low as $\alpha=.14$ (ORTO-15) up to $\alpha=.86$ (ORTO-11). Based on
270 the RG with 24 reported Cronbach's alpha values, the population alpha for the 15-
271 item version following the original scoring instructions was identified as $\alpha_p=.62$. Even
272 though recommendations for the satisfactory level of Cronbach's alpha values differ,
273 an alpha value below $\alpha=.70$ is consistently seen as questionable (DeVellis, 2003;
274 Bland & Altman, 1997; Nunnally, 1967 in Tavakol & Dennick, 2011). The test re-test
275 reliability for the individual items of the ORTO-15 had only been assessed by two
276 studies using Cohen's kappa, suggesting mixed results. However, the kappa
277 coefficient was designed to measure observer agreement (Landis & Koch, 1977)
278 rather than score repeatability. Using Cohen's kappa for the estimation of test re-test
279 reliability violates the assumption of independent raters (Cohen, 1960) and is
280 therefore not conclusive.

281 The ORTO-15 was designed to measure three dimensions: cognitive-rational, clinical
282 and emotional aspects of ON. However, the factorial structure of the questionnaire
283 remains uncertain. A single-factor, 2-factorial and 3-factorial structure have been
284 proposed for different item-lengths of the scale. Only one study had evaluated the
285 original 15-item version regarding its dimensionality, which identified a 3-factorial
286 structure for the scale. All other studies evaluating the ORTO-15 reduced the item-
287 length in order to improve its model fit.

288 Regarding the ORTO's construct validity, the only pattern identifiable was its
289 consistent negative correlation with established tools measuring disordered eating.
290 Higher ORTO-scores indicate less ON tendencies. This interpretation is not
291 consistent across all included studies, making the interpretation of associations
292 difficult. The values cover low, moderate and even large correlations, depending on
293 the ORTO version utilized. Greater ON tendencies were weakly to moderately

294 associated with higher symptoms of depression and OCD (for shorter item-versions
295 of the ORTO).

296 **3.2.9 Scale to Measure Orthorexia in Puerto Rican Men and Women (k=1)**

297 The internal consistency for the Puerto Rican ON scale has only been assessed by
298 the measure's authors. The Cronbach's alpha values range from questionable
299 ($\alpha=.66$ for "Lifestyle") to good ($\alpha=.84$ for "Food Intake"). The total scale had a good
300 internal consistency ($\alpha=.87$). The authors identified a 5-factorial structure. No
301 information was available on the measure's construct validity.

302 **3.2.10 Teruel Orthorexia Scale (TOS, k=2)**

303 The TOS shows good internal consistency values for both subscales, "Healthy
304 Orthorexia" (Cronbach's $\alpha=.80$ to $\alpha=.87$) and "Orthorexia Nervosa" ($\alpha=.81$ to
305 $\alpha=.90$). The re-test reliability after 18 months was $r>.70$ for both subscales, according
306 to one study. Even though a 2-factorial structure is theoretically meaningful, a 4-
307 factorial solution and cross-loadings between the two subscales need to be
308 investigated in future studies based on previous findings. Correlations with tools for
309 disordered eating were positive for both subscales (moderate correlations for
310 "Healthy Orthorexia" and moderate to high for "Orthorexia Nervosa"), unless the
311 other subscale was partialled out, which reversed and attenuated the correlational
312 relationship for "Healthy Orthorexia" to "Bulimia" (EAT-26) and other subscales
313 measuring disordered eating, negative affect and perfectionism. Partialling out
314 "Healthy Orthorexia", did not change the relationship between "Orthorexia Nervosa"
315 and OCD-symptoms, disordered eating behaviors and perfectionism, but increased
316 the positive correlation with negative affect.

317 **4 Discussion**

318 This systematic review collated all available information on the psychometric
319 properties of ten quantitative ON measures, in order to illustrate weaknesses and
320 strengths of existing ON tools. The review had two key findings. First, only 68 out of
321 the 141 (48.23%) identified studies reported at least one of the specified
322 psychometric quality assessments. This finding is surprising, as there is no 'gold
323 standard' or commonly accepted definition of ON (e.g. Cena et al., 2018)
324 complicating any validity judgements. The lack of exhaustive reliability analyses
325 suggests that prevalence rates and ON-risk assessments could be highly affected by
326 measurement errors. Reporting different reliability scores is important, as they
327 represent different cumulative sources of measurement error (e.g. Henson, 2001).
328 More transparency regarding measurement properties should be displayed, as they
329 are essential for researchers choosing their measures.

330 The second finding of this review concerns the measures' reported psychometric
331 properties. Based on the present analysis, utilizing the BOT or the ORTO for the
332 assessment of ON is discouraged. This finding is in line with previous studies
333 advising against the use of the ORTO-15 (Dunn & Bratman, 2016; Missbach, Dunn &
334 König, 2017; Cena et al., 2018) and BOT (Eriksson et al., 2008) for assessing ON.
335 The original questions of the BOT were designed as a personal risk assessment,
336 which were updated by Bratman to become the 'The Authorized Bratman Orthorexia
337 Self-Test' (Bratman, 2017a). However, the original questions were never intended to
338 be used as an assessment tool (Bratman, 2017), as the BOT has no test-theoretical
339 foundation, which is reflected in its questionable dimensionality. It is not clear how
340 many of the BOT items refer to ON-specific behaviors and thoughts or general eating
341 pathology. The ORTO-15 had to be adapted by multiple studies to obtain acceptable
342 psychometric properties, in most cases by means of excluding a considerable

343 number of items. Furthermore, the inconsistent findings regarding the ORTO's
344 construct validity suggest either problems with the conceptualization of the ORTO
345 and/or common misinterpretations of score results.

346 Promising findings were identified for the DOS, the EHQ-R and the TOS, even
347 though further validation in various (cultural) contexts are needed. For example, the
348 DOS shows good reliability, however, most of its evaluations were carried out by the
349 scale's author within German study samples and need to be replicated in other
350 settings. Furthermore, the scale's dimensionality remains inconclusive, with a single
351 factor being meaningful but mostly poorly fitted.

352 The B-ORA and the ONS were both designed and published in the framework of a
353 thesis and will require further evaluation. Finally, the Puerto Rican tool and the BISQ
354 ON-subscale were designed for specific cultural contexts. At this point, it is not
355 recommended to apply these scales without further validation.

356 Some of the measurement difficulties identified may reflect a lack of conceptual
357 clarity regarding ON more generally. The findings regarding the DOS's high
358 correlations with measures for weight and shape concerns deviate from the common
359 perception that ON is not related to an intentional weight loss (e.g. Dunn & Bratman,
360 2016). Moreover, it remains to be clarified what constitutes a pathological approach
361 to healthy eating. Feelings of superiority regarding one's healthy diet, for example,
362 were originally seen as a core element of the clinical picture (Bratman & Knight,
363 2000) describing ON. Within the TOS, items related to feelings of superiority are
364 conversely seen as part of "Healthy Orthorexia".

365 This systematic review identified all measures published at the time of the analysis.
366 New measures are continuously being developed, such as the Barcelona Orthorexia

367 Scale (BOS, Bauer et al., 2018), which is based on a Delphi study methodology, and
368 the Orthorexia Nervosa Inventory (ONI, Oberle, De Nadai & Madrid, 2020). The ONI
369 combines adapted items from the DOS and EHQ with novel items to represent
370 coinciding diagnostic criteria of ON. A first validation study indicated high internal
371 consistency values (Cronbach's $\alpha = .94$ for ONI_{total} , $\alpha > .88$ for all subscales) and
372 high positive correlations with the EAT-26 ($r = .79$ for ONI_{total}) and the Yale-Brown
373 Obsessive-Compulsive Scale ($r = .53$). The new scale construction approaches are
374 promising as they are combining various expert opinions. However, this review has
375 shown that there are conceptual differences among ON scales that represent
376 disparate expert opinions and need to be addressed. Evaluating and comparing ten
377 ON scales revealed the individual strengths and weaknesses of the measures and
378 will provide guidance for future research within the field.

379 **5 Strengths and Limitations**

380 Even though past reviews have scrutinized ON research, no study so far
381 exhaustively evaluated the psychometric properties of all ON assessment tools. The
382 present systematic review included all empirical studies assessing ON, which were
383 published in English, German, French, Dutch or Spanish up to the end of August
384 2019. Even though articles written in multiple languages were included in this review,
385 twelve studies were not assessed due to being written in Portuguese, Italian, Polish
386 or Swedish. Excluding these articles might have introduced a language bias
387 considering that the presented results varied across different language versions.
388 The RG analysis in this systematic review could have been influenced by the so-
389 called "file drawer problem" (Rosenthal, 1979; Howell & Shields, 2008). Only about
390 half of the studies that assessed ON with a quantitative measure reported score

391 reliabilities. This problem was partly addressed by contacting authors via email if any
392 information was missing or ambiguous, which resulted in additional information being
393 provided by 16 authors.

394 The studies included in this review were heterogeneous in many respects, including
395 their conceptualization of ON, their assessment method and their study samples.

396 This heterogeneity made a comparison difficult and results should be interpreted
397 bearing in mind that study designs and approaches greatly varied between studies.

398 The goal of this review was not to evaluate the quality of included studies'
399 methodological approaches, but rather contrasting the information provided
400 regarding reported psychometric properties.

401

402

403 **6 Conclusion**

404 The analysis of reliability and validity indicators of ON measures demonstrated that
405 existing tools exhibit either questionable psychometric properties (BOT, ORTO-15),
406 challenge preliminary diagnostic criteria (DOS, TOS) or require further evaluation
407 (e.g. EHQ-R, ONS, B-ORA). A surprising and concerning finding of this review refers
408 to the lack of reporting in relation to psychometric properties, considering that no
409 gold standard exists for the measurement of ON. Further research is needed to
410 clarify current inconsistencies in the conceptualization of ON, which are reflected in
411 its measurement tools. Additionally, future studies need to be more transparent
412 about the process of test construction and evaluation, if we want to improve the
413 research surrounding ON. Potential implications of this analysis are therefore the
414 need for more rigorous evaluation processes for new and existing scales across

415 settings and cultural contexts, recognizing the provisional nature of any research
416 findings associated with scales intending to measure ON and the necessity of
417 researchers and practitioners to address current contradictions in the
418 conceptualization of ON.

419 **Acknowledgement**

420 We would like to thank Dr Friederike Barthels and Tobias Thomas for providing us
421 with unpublished data. Furthermore, we would like to thank Dr David Gleaves and Dr
422 Radoslaw Rogoza for providing unpublished material to include in our analysis.

423 **Author Contributions**

424 All authors have approved the final article for publication. MCO, HS and EN
425 designed the study, MCO, ASAVM and MR conducted the searches, MCO drafted
426 the manuscript, HS and EN provided revisions to the manuscript.

427 **Disclosure**

428 The authors of this review have no conflict of interest to declare. Ethical approval
429 was not required, as this was a review study.

430 **Funding Sources**

431 This research did not receive any specific grant from funding agencies in the public,
432 commercial, or not-for-profit sectors.

Table 1 Identified ON Measures

Tool	Author(s) and Year	Country	Conceptual Framework	Measurement Aim	Format and Practicalities	Target Population	Item Selection Strategy	Language Adaptations
Body Image Screening Questionnaire (BISQ)	Jenaro Río et al. (2011)	Spain	Conceptualizing eating disorders from a comprehensive perspective, which considers ON and Vigorexia as part of the eating disorder spectrum	Designing an early detection tool for different eating disordered behaviors	24-items (total scale); 5 items to measure ON, scored on a 6-point Likert scale	Evaluated within a population of participants considered as at-risk for disordered eating behaviors and a general population sample	Clinical criteria to identify ON evaluated by four experts in the field of eating disorders	---
Burda Orthorexia Risk Assessment (B-ORA)	Burda (2018)	United States	Exploring cognitive, emotional, and behavioral themes leading to problematic ON-related eating habits	Not a diagnostic tool; providing information for clinicians to detect unhealthy eating behaviors and phobic-obsessive personality traits associated with ON	27 items (21 ON-related tendencies, 6 control questions, which are not scored; 4-point Likert scale ('I strongly disagree' to 'I strongly agree'))	College students within the United States	Items based on proposed diagnostic criteria by Dunn & Bratman (2016) and Moroze et al. (2015), as well as ON-specific patterns of thoughts, emotions and behaviors as presented in the literature	---
Bratman Orthorexia Test (BOT)	Based on the informal personal	United States	ON as a fixation on/obsession	Identifying potential	10 dichotomous questions, which can be	People being overly	The content of the self-assessment	German (Kinzl et al. (2005), Swedish (Eriksson et al.,

	risk-assessment quiz originally published in "Health Food Junkies" (Bratman & Knight, 2000)		with eating healthy food	problems with food habits	answered with either 'yes' or 'no'; scoring differs between authors	concerned with healthy nutrition	questions are based on the personal as well as professional experiences of Steven Bratman, who first coined the term ON in 1997	2008) Greek (Grammatikopoulou et al., 2018), with differing score interpretations
Düsseldorf Orthorexia Scale (DOS)	Barthels, Meyer & Pietrowsky (2015a)	Germany	Measuring a potentially pathological fixation on a health-conscious diet, considering cultural particularities	Assessing orthorexic eating behaviors with discriminatory power, based on test-theoretical considerations	10-items; 4-point Likert scale ('does not apply to me, 'rather does not apply to me' to 'rather applies to me' and 'applies to me'); preliminary cut-off at 30 points	General German Population	Inductive item generation involving relevant eating behaviors and attitudes towards nutritional knowledge, taking into account the case studies in Bratman and Knight (2000).	English (Chard et al., 2018), Chinese (He et al., 2019), Spanish (Parra-Fernandez et al., 2019)
Eating Habits Questionnaire (EHQ)	Graham (2005); Gleaves et al. (2013)	United States	ON as "[...] an otherwise healthy behavior [...] taken to extremes [...]" (Gleaves et al., 2013, p. 1).	Measuring a pathological fixation on eating healthy food	21-item scale; 4-point Likert scale ('false, not at all true' to 'very true'); three subscales (problems associated with healthy eating, knowledge of healthy eating and feeling positively about healthy eating);	Validated with a population of college students studying psychology or nutrition	The original item pool was generated according to the information provided in the book "Health Food Junkies" and evaluated by four graduate students trained in ON symptomatology to select items	Italian (Novara et al., 2017; not included in this review as only available in Italian)

					higher values indicate more ON symptoms		accurately representing ON	
Eating Habits Questionnaire-Revised (EHQ-R)	Glen & Gleaves (2018)	Australia	Considering impairments and negative emotionality associated with ON; including the proposed diagnostic criteria by Dunn & Bratman (2016)	To extend and update the EHQ in order to identify the underlying factors describing ON	30 items; five factors: rigidity (7 items), healthy body image (6 items), violation of dietary rules (7 items), negative emotionality (6 items), time impairment (4 items)	General Australian Population	25/30 based on Dunn & Bratman (2016) criteria and ON research; 5 items from the EHQ	---
Orthorexia Nervosa Scale (ONS)	Kramer (2016)	United States	ON as associated with superiority, downward social comparison, rigidity, purity, social avoidance, identity, eating disorder as meaning, loss of control, preoccupation, eating to cope, nutritional deficiencies and relationship problems	Assessing current behavioral tendencies associated with ON	47 items with 10 dimensions; 5-point Likert-scale ("Strongly Disagree", "Disagree", "Neither Agree or Disagree", "Agree", "Strongly Agree")	Developed and evaluated with a college student sample	Items based on previous questionnaires (ORTO-15, EHQ, BOT) and a literature review on ON combined with the consultation of colleagues familiar with the content area	---
ORTO-15	Donini et al. (2004; 2005)	Italy	ON as a "[...] more or less serious personality or behavioral	Measuring cognitive-rational, clinical and emotional aspects of ON	15 items scale with a closed multiple-choice format ('always', 'often',	Italian general population	6/15 items based on questions from Bratman's Orthorexia self-	Turkish (Arusoglu et al., 2008), Polish (Brytek-Matera et al., 2014b), Hungarian (Varga

			disturbance [...]” (Donini et al., 2004, p. 151).		‘sometimes’, ‘never’. Higher values indicate healthier behaviors. For items 1 and 13, the highest values are assigned to the answers ‘often’ (4) and ‘sometimes’ (3); cut-off <40 points to indicate a potential diagnosis		test, with some of the wordings changed; preliminary versions of the questionnaire were piloted to create the final measurement tool	et al., 2014), German (Missbach et al., 2015), Spanish (Parra-Fernandez et al., 2018), English (Heiss, Coffino & Hormes, 2019) and Arabic (Haddad et al., 2019)
Scale to Measure Orthorexia in Puerto Rican Men and Women	Carrero, Cotto & Rodriguez-Gomez (2016)	Puerto Rico	Designing a measure for ON, which is applicable in the Latin American context; ON defined according to Bratman (1997)	Assessing ON within a Latin American population including behaviors, thoughts, feelings, perceptions and symptomatology	The five subscales “Food Intake”, “Obsession”, “Lifestyle”, “Social Isolation” and “Pollution and Compulsion” constitute the measure. The 27-item tool uses a 4-point Likert scale (‘never’ to ‘always’), with higher values representing a higher ON symptomatology	Puerto Rican men and women	Items are based on ON research and an expert rating, including raters with experience in psychology, in the field of eating disorders and in evidence building	---

Teruel Orthorexia Scale (TOS)	Barrada & Roncero, (2018)	Spain	Orthorexia seen as either a tendency and interest in eating healthy food (HeOr) or a pathological preoccupation with a rigid healthy diet (OrNe)	Measuring both problematic and non-problematic healthy eating behaviors and differentiating between the two	17 items measuring two dimensions: "Healthy Orthorexia" (HeOr, 9 items) and "Orthorexia Nervosa" (OrNe, 8 items); 4-point rating scale ('completely disagree' to 'completely agree'); higher values indicate a higher expression of either HeOr or OrNe.	Validated with primarily university student sample	An initial item pool for the scale was generated to represent the previous literature on ON, which was then reduced based on the principle of statistical simplicity	---
