Recent research has shown dramatic improvements in the performance of band-edge lasers made from dye-doped chiral nematic liquid crystals (LCs) [1]. Continuously-tuneable laser emission is possible across the entire visible spectrum [2] and the near-infrared [3], from 450 to 850 nm, with efficiencies of more than 60%. Their compact and simple construction mean that low-cost, portable, tuneable lasers are now achievable. This technology enables the miniaturisation, cost-reduction and functional enhancement of many laser-based techniques, particularly for biomedical applications including fluorescence microscopy (e.g. Raman, flow cytometry, confocal, etc.). Advances towards laser-diode pumping and printable LC lasers offer us further size and cost reductions, and may ultimately enable the development of hand-held optical tools, for point-of-care medical diagnosis. We thank the EPSRC for funding of the COSMOS Technology Translation award (EP/H046658/1).
