Abstract: Objectives: Findings regarding the benefits of fruit and vegetables (FV) on weight control are inconsistent and little is known among Chinese populations. Therefore, we examined the relationship between change in FV consumption, weight and change in body mass index (BMI) among Chinese adults, participants of the China Health and Nutrition Survey (CNHS).

Study design: A prospective cohort study.

Methods: Two waves of CNHS conducted in 2006 and 2011 were used. Continuous FV consumption increase was considered as the exposure and changes in weight and BMI as outcomes. Change in FV consumption was categorized into quintiles. Analysis of covariance and multiple linear regression models, after controlling for potential confounders such as energy intake, physical activity, and smoking, were used to describe the relationship between change in FV consumption and change in weight and BMI.

Results: A total of 4357 participants aged 18-65 years were included in this study. The respective weight and BMI gains in male individuals were 1.81 kg and 0.73 kg/m² in the fifth quintile of FV change relative to individuals in the first quintile (3.67 kg for weight gain and 1.48 kg/m² for BMI gain). An increase in FV consumption by 100 grams was associated with a 211 g weight loss (B= -2.11; 95% CI, -3.34,-0.89, p<0.001) and a decrease in BMI by 0.94 kg/m² (B= -0.94; 95% CI, -1.36,-0.46, p<0.001) in men; and a 140 g weight loss (B= -0.14; 95% CI, -0.97, 0.69, p=0.74) and a decrease in BMI by 0.29 kg/m² BMI (B= -0.29; 95% CI, -0.63, 0.06, p=0.11) in women.

Conclusions: Increase in FV consumption was associated with statistically significant weight loss and decrease in BMI among Chinese men, and, although suggested, weight loss among women was not significant. Considering the protective effect of FV on human health, increasing FV consumption in Chinese population is recommended.
Dear Sir or Madam,

I would like to submit the following manuscript for possible evaluation.

Manuscript (Original research) Title: The association of fruit and vegetables consumption with changes in weight and body mass index in Chinese adults: a cohort study

The prevalence of overweight and obesity has increased substantially in the past few decades worldwide. Obesity is a multi-factorial, complex condition, and no single intervention will be sufficient to prevent it. Multiple strategies are needed and one of such identified strategies includes increase in fruit and vegetables (FV) consumption. However, findings regarding the benefits of FV on weight control were inconsistent.

We assessed the relationship of FV intake with changes in body weight and BMI over a 4.6-year period in a large Chinese adult cohort. A total of 4357 participants aged 18-65 years were included in this study. The respective weight and BMI changes in male individuals were 1.81 kg and 0.73 kg/m² in the top quintile of FV change relative to individuals in the bottom quintile (3.67 kg for weight change and 1.48 kg/m² for BMI change). Increased one kilogram FV consumption was associated with a 2.11 kg weight loss (95% CI, -3.34, -0.89, p<0.001) and a 0.94 kg/m² BMI loss (95% CI, -1.36, -0.46, p<0.001) in men and a 0.14 kg weight loss (95% CI, -0.97, 0.69, p=0.74) and a 0.29 kg/m² BMI loss (95% CI, -0.63, 0.06, p=0.11) in women.

In conclusion, there was an inverse relationship of FV consumption with weight and BMI change among Chinese men. Protective effect of FV intake was also noted among women though not statistically significant. Considering the protective effect of FV consumption in human health and disease prevention, increasing FV consumption in Chinese population should be recommended.

I affirm that the manuscript is original research, and has been prepared in accordance with your Instructions to authors. The authors have no conflicts of interest. I also confirm that I full access to all aspects of the research and writing process, and takes final responsibility for the paper.

I have read the manuscript and I hereby affirm that the manuscript has been submitted solely to Public Health. The content of this manuscript or a major portion thereof has not been published previously, either in whole or in part, nor have the findings been posted online, and it is not being submitted for publication elsewhere, and each author has seen and approved the consents of the submitted manuscript.

Thanks very much for your attention to our paper.

Sincerely yours,

Qi-qiang He, PhD/Professor

Abstract

Objectives: Findings regarding the benefits of fruit and vegetables (FV) on weight control were inconsistent and little was known among Chinese populations. Therefore, we examined the relationship between change in FV consumption and weight and change in body mass index (BMI) change among Chinese adults, participants of the China Health and Nutrition Survey (CNHS).

Study design: A prospective cohort study.

Methods: Two waves of CNHS China Health and Nutrition Survey (CNHS) conducted in 2006 and 2011 were used. Continuous FV consumption increase was considered as the exposure and changes in weight and BMI changes as outcomes. Change of FV consumption was categorized into quintiles. Analysis of covariance and multiple linear regression models, after controlling for several potential confounders such as energy intake, physical activity, and smoking, etc., were employed to investigate the relationship between change in FV consumption and change in weight and BMI change.

Results: A total of 4357 participants aged 18-65 years were included in this study. The respective weight and BMI gains in male individuals were 1.81 kg and 0.73 kg/m^2 in the fifth quintile of FV change relative to individuals in the first quintile (3.67 kg for weight gain and 1.48 kg/m^2 for BMI gain). An increase in FV consumption by 100 grams FV consumption was associated with a 211 g weight loss (B=-2.11; 95% CI, -3.34,-0.89, p<0.001) and a decrease in BMI by 0.94 kg/m^2 BMI loss (B=-0.94; 95% CI, -1.36,-0.46, p<0.001) in men; and a 140 kg weight loss (B=-0.14; 95% CI, -0.97, 0.69, p=0.74) and a decrease in BMI by 0.29 kg/m^2 BMI loss (B=-0.29; 95% CI, -0.63, 0.06, p=0.11) in women.

Conclusions: Increase in An inverse association between FV consumption was associated with statistically significant weight loss and decrease in BMI gain was found among Chinese men, and, although suggested, weight loss among women, was not significant. Considering the protective effect of FV on human health, increasing FV consumption in Chinese population should be recommended.
Keywords: Adult; fruit and vegetables; weight; BMI.
Introduction

The prevalence of overweight and obesity has increased substantially in the past few decades worldwide\(^1,2\). It was estimated that the proportion of overweight adults increased from 28.8% in 1980 to 36.9% in 2013, which exacted a huge\(\text{substantial}\) burden on people’s health globally\(^3\). Obesity has been linked to an increased risk for cardiovascular diseases (CVD), diabetes, some types of cancers, and osteoarthritis\(^4\). Considering the challenges in treating obesity and achieving weight maintenance, there is an urgent need for obesity prevention approaches across populations.

Obesity is a multi-factorial, complex condition, and no single intervention will be sufficient to prevent it. Multiple strategies are needed and one of such identified strategies includes an increase in fruit and vegetables (FV) consumption\(^5\). It has been observed that increased FV consumption may reduce the risk of CVD, diabetes, and certain cancers\(^6\). However, findings regarding the benefits of FV on weight control were inconsistent. While some studies reported that increased FV consumption reduced weight or body mass index (BMI)\(^7-9\), others noted no such relationship\(^10,11\).

With rapid economic growth and industrialization\(^12\), a dramatic rise in the prevalence of overweight and obesity was observed among Chinese adults posing a major threat to their health\(^13\). Simultaneously, data suggest a reduction of vegetable consumption among this population. According to a recent study in China, vegetable consumption of Chinese citizens decreased from 363.4 g/day in 1993 to 321.6 g/day in 2011, whereas it was reported that Chinese people ate only 90.1g fruit daily in 2011\(^14\). Although some cross-sectional studies have explored the effects of dietary pattern on obesity among Chinese adults\(^15,16\), the longitudinal association between FV consumption and obesity has not been investigated. Therefore, we assessed the relationship of the change in FV intake with changes in body weight and BMI over a 4.6-year period in a large cohort of Chinese adult cohort.

Methods

Study design and participants

The China Health and Nutrition Survey (CHNS) is an ongoing prospective
cohort study with data from 1989 to 2011 available for public use. The CHNS was designed to provide representation of rural, urban, and suburban areas varying substantially in geography, economic development, public resources, and health indicators. A multistage random-cluster sampling method was employed to recruit subjects. The original survey sites included eight provinces: Liaoning, Jiangsu, Shandong, Henan, Hubei, Hunan, Guangxi, and Guizhou; a 9th province, Heilongjiang, was added in 1997. Counties in the nine provinces were stratified by income (low, middle, and high) and a weighted sampling scheme was used to randomly select four counties in each province. Two cities (the provincial capital and a lower income city) and four economically striated counties were selected in each province. Within cities, two urban and two suburban communities were selected; and within counties, one community in the capital city and three rural villages were chosen. Details of the study design and recruitment methods have been described elsewhere. The present study was based on 2006 wave and 2011 waves of the CHNS. Written informed consent was provided by each participant. The study protocol for this study was approved by institutional review boards of University of North Carolina at Chapel Hill, and National Institute for Nutrition and Health, Chinese Center for Disease Control and Prevention.

Outcomes

The outcomes of the study include changes in weight and BMI between years 2006 and 2011. Participants’ height and weight at baseline and follow-up were measured by trained technicians using standard methods. Weight was measured with participants in light clothing to the nearest 0.1 kg. Individual’s height was measured to the nearest 0.1 cm with participants being barefoot. BMI was defined as body weight in kilograms divided by the square of height in meters.

Exposure

The exposure was defined as change in FV consumption (g/day) between years 2006 and 2011. FV consumption was assessed by three consecutive 24-hour dietary recalls, which included two week days and one weekend day. Individuals were asked about the exact type and weight of food they consumed by trained interviewers.
including food consumed away from home. A food system was specifically developed
for CHNS and Chinese Food Composition Tables, which included 162 fruit items and
256 vegetable items\textsuperscript{19}. The average daily FV intake was derived from participant
responses.

Confounders

Information on gender, age, education, province, and lifestyle were collected
from self-administered questionnaires. Education level was defined as the highest
education the participants received. Lifestyle measures included physical activity (PA),
energy intake (EI), smoking status, alcohol and soft drink consumption. PA level was
calculated by multiplying the weekly time spent in each activity by metabolic
equivalent (MET) score, an indicator of average intensity of each PA\textsuperscript{20}. In this study,
we defined PA as the leisure PA domain according to the SLOTH model\textsuperscript{21}, containing
13 items of active and sedentary leisure. Energy intake (EI) was measured by
aggregating the energy contained in each food daily consumed based on Chinese Food
Composition Tables. The information of smoking status, alcohol and soft drink
consumption were collected through a self-reported questionnaire. Current smoking
was assessed by two questions. Participants were first asked to report whether they
ever smoked. If yes, they were asked by a following question that if they still smoked.
Respondents—Individuals who reported ever smoking and still smoked were
considered as “current smoking”. Alcohol consumption was assessed by the question
“Did you ever drink alcohol (beer, white wine or other spirits) in the last year?” If yes,
they were defined as “current alcohol consumption”. Soft beverage consumption was
first assessed by the question “Did you consume soft drinks or sweetened beverage in
the last year?” If yes, participants were asked to report the frequency of soft drinks
and sweetened beverage. The response options included “daily”, “3-4 times per week”,
“1-2 times per week”, “1-3 times per month”, “less than one times per month”, and
“unknown”. Those who reported consuming soft drinks and sweetened beverages for
more than 3 times per week were classified as soft drink consumption. We used the
mean values of two waves to represent EI and PA level in the entire period
(2006-2011), however, for smoking status, alcohol and soft drink consumption, we
used two waves’ information to represent them.

Statistical analysis

Sex differences in baseline characteristics were examined using t-test and a chi-square test for continuous and categorical variables, respectively. Change of FV consumption was categorized into quintiles. The difference in weight and BMI change across quintiles of FV was assessed by analysis of covariance (ANCOVA) with adjustment for confounders. In addition, three multivariable linear regression models were employed to determine the relationship between FV consumption and changes in weight and BMI: Model 1, adjusted for age (years); Model 2, adjusted for age and baseline BMI (kg/m²); and Model 3, additionally adjusted for other confounding factors including province, education level, EI, PA, smoking status, alcohol consumption and soft drink consumption. All statistical analyses were performed by using the SPSS statistical package (version 13.0; SPSS Inc., Chicago, IL, USA) stratified by sex group.

Results

Of the 4793 participants aged 18 to 65 years in 2006 who had complete data on FV intake and anthropometric measurements in both surveys, 436 were excluded because of pregnancy (n=31), type 2 diabetes (n=129), cancer (n=42), CVD (n=110), and extreme EI (<500 kcal/day and/or >4000 kcal/day) (n=124). Finally, a total of 4357 participants were included in this study.

Baseline characteristics of participants are shown in Table 1. Mean age of men (45.8 years) did not significantly differ from that of women (46.4 years). Compared to men, women were more likely to report completing less than high school education. EI, FV intake and weight were on average higher in men than in women. There was a significant sex difference in smoking status and alcohol consumption whereby men, compared to women, were more likely to report current smoking and alcohol consumption. In contrast, women were more than men to report soft drink consumption. No sex difference was observed for BMI and PA.

Sex-specific change in weight and BMI by FV change quintiles from 2006 to
2011 are displayed in Figure 1 (Q1≤-0.2, Q2≤-0.05, Q3≤0.667, Q4≤0.2233, Q5>0.2233). There was an significantly inverse relationship between increases change in FV consumption and weight and BMI change during the study period in men. The weight and BMI changes in male individuals were 1.81 kg and 0.73 kg/m² in the Q5 of FV change relative to individuals in the Q1 (3.67 kg for weight change and 1.48 kg/m² for BMI change). Compared with those with the lowest FV change quintile, women in the highest FV change quintile showed a lower average BMI gain, however the results did not meet even though statistically insignificance. However, this trend in weight gain was not found observed.

The results of multiple linear regression analysis of the relationship between change in FV intake and change in weight and BMI in men and women are presented in Table 2. In men, there was a negative association between change in FV consumption and change in weight and BMI whereby for each 100 grams increase in FV intake, individual’s weight would decrease by 211 g (B=-2.11; 95% CI: -3.34,-0.89) and BMI would decrease by 0.94 kg/m² (B=-0.94; 95% CI: -1.36,-0.46). Although a similar relationship was observed in women, the results were not statistically significant.

Discussion

In this prospective cohort study of 4357 Chinese men and women, an inverse association was observed between change in FV and weight and BMI change in Chinese men. The findings were independent of age, baseline BMI, education level, province, EI, PA, smoking status, and alcohol and soft drink consumption. The findings in women followed the same pattern of those of men, although however the results did not reach statistical significance.

Previous results regarding the association of FV consumption and body weight and BMI were inconsistent. A meta-analysis of human randomized controlled trials concluded that there was no empirical evidence that increasing FV would have a discernable effect on body weight. Another systematic review suggested that the inverse relationship between FV consumption and adiposity among overweight adults
was weak. However, a recent meta-analysis showed that high intake of fruits was inversely associated with weight change, although no significant changes were observed for vegetable or combined FV consumption. Furthermore, our findings lend support to several epidemiological studies that revealed an inverse association between FV consumption and weight and BMI gain. In a 14-year study of American adults, Bertoia et al. reported that one daily serving increase in total fruits and total vegetable consumption was associated with 0.53 lb and 0.25 lb body weight loss, respectively. Similarly, while studying a European population, Buijsse et al. observed weight loss of 14 grams per year per each 100 grams increase in FV intake during a 6.5-year follow-up. Results for the equivocal results may include the different types of design, dietary assessments, and various covariates. Therefore, further high-quality research with long duration follow-up is still needed to confirm our findings.

In the present study, we found sex-specific relationships between FV consumption change and weight and BMI change among Chinese adults. The results were in line with several studies that reported a less significantly inverse relationship between FV consumption and weight gain among women compared to men. A large Mediterranean population study reported that a significantly inverse association between FV consumption and weight gain was observed only among men. However, similar relationships, in direction and magnitude, for men and women were found between dietary factors and weight change in three US cohorts. Potential reasons for sex difference of the associations between FV consumption and weight and BMI gain might be explained by less vegetables consumption in women compared to men. Furthermore, different socioeconomic factors and hormone level between genders could also influence weight gain.

There are several hypothetical mechanisms by which FV may be protective against obesity risks. One potential explanation for weight reduction by FV consumption may be a decrease in the total energy intake and a consequent amelioration of energy disequilibrium. Furthermore, several components of FV, such as fiber content, glycemic load (GL) and biologically active substances (e.g. polyphenols), might also responsible for their anti-obesity effects. Most FVs are rich
in fiber and active constituents and have a low GL. Fibers in FV increase satiety, reduce hunger feeling and energy intake and prevent weight gain. Additionally, lower-GL of FV produces fewer and smaller postprandial glucose spikes that may decrease subsequent hunger and reduce total energy intake. Also, low-GL or low-glycemic-index (GI) diets may increase resting energy expenditure, promoting weight maintenance according to a clinical trial evidence. Moreover, polyphenols may influence insulin sensitivity, the gut microbiome, or the anabolic state of adipose tissue, which could contribute to the weight control in the long term.

To the best of our knowledge, the present study was among the first to investigate the longitudinal relationship of FV consumption with weight and BMI change among Chinese adult population. Nevertheless, there are several limitations in our study. First, FV intake assessment using 24-h dietary recall may yield measurement error. Nevertheless, this would be random error and tend to underestimate the relationship of FV intake with weight change. Second, MET hours per week could not actually reflect the energy cost of PA in individuals. However, it is useful for providing population-based PA estimates. Third, although several covariates have been adjusted in our results, we could not exclude the possibility that the observed association may have been affected by some residual confounding factors. Last, we only included participants aged 18 to 65 years in 9 provinces, thus the results may not be generalizable to all Chinese adults.

In conclusion, there was an inverse relationship of FV consumption with weight and BMI change among Chinese men. Protective effect of FV intake was also observed among women though not statistically significant. Considering the protective effect of FV consumption in human health and disease prevention, increasing FV consumption in Chinese population should be recommended.

Fruit and vegetables consumption (quintile)
Highlights

- We examined the association between weight and BMI increase and fruit and vegetables intake in Chinese adults.
- Data collected from the China Health and Nutrition Survey (2006 to 2011) were analyzed.
- Chinese men with lower fruits and vegetable intake showed higher risks for weight and BMI gain compared with the counterparts with higher intake.
